Just 2 years later, Louis himself found the skull of *Homo habilis* in the same rock strata at Olduvai Gorge; it is a far more hominid form than “Zinj” and is directly associated with the pebble culture of the Oldowan tradition, consisting of the earliest human-made stone implements of cores and flakes known at that time (although it is arbitrary when the designation “human” may be first applied to the very long, branching, and complex process of hominid evolution).

In 1972, at Koobi Fora on the eastern shore of Lake Turkana in northwestern Kenya, Richard Leakey discovered the famous *Homo habilis* skull 1470, dating back about 1.9 million years. Therefore, both at the Olduvai Gorge and Koobi Fora sites, the larger-brained *Homo habilis* is associated with the dawn of human-manufactured Paleolithic culture.

In 1974, at the Hadar site in the Afar Triangle of northern Ethiopia, Donald C. Johanson found the fossil hominid “Lucy” skeleton. This specimen was dated at over 3 million years old. Although the skull and teeth of *afarensis* have apelike characteristics, the postcranial skeleton is truly hominid. An analysis of the postcranial

bones revealed that “Lucy” stood erect and walked upright with a bipedal gait. Classified as *Australopithecus afarensis*, this remarkable discovery clearly demonstrated that bipedalism had been established in hominids before the end of the Pliocene epoch.

In 1978, at the Laetoli site, south of Olduvai Gorge, Mary Leakey had the incredible good fortune to find three tracks of hominid footprints about 3.6 million years old. According to Johanson, these Laetoli tracks were made by *Australopithecus afarensis* (for him, the common ancestor of all later hominids). In 1995, these Pliocene footprints were reexcavated and reexamined. Then, the three Laetoli tracks were carefully reburied in order to preserve this unique discovery for centuries to come.

In science, nothing succeeds like success. The more paleoanthropologists search for fossil hominids in central East Africa, the more evidence they find. Recent discoveries by Tim White and Meave Leakey have pushed back the beginning of hominid evolution to over 4.4 million years ago. These earliest bipedal hominid forms are represented by *Ardipithecus ramidus* (a side branch in hominid evolution found in Ethiopia) and the later *Australopithecus anamensis* from Kenya, a species ancestral to *Australopithecus afarensis*.

In 1999, fossil hominid evidence from the Bouri site, south of Aramis, in Ethiopia, was dated to about 2.5 million years old. This latest discovery is designated *Australopithecus garhi* and is another illustration of Plio-Pleistocene hominid species diversity in Africa.

Also, in 1999, at a site in Northern Kenya near the western shore of Lake Turkana, a research team headed by paleontologist Meave Leakey discovered an unusual million-year-old skull. The near-complete cranium shows both hominid-like and pongidlike characteristics: small brain, small teeth, and human-looking but flat face. It is classified *Kenyanthropus platyops*, denoting both a new genus and new species among the early fossil hominids of central East Africa (thereby separating this form from the *Australopithecus afarensis* specimens found at Hadar and Laetoli). If more fossil hominid species from this time period are found, then those complex questions that still concern the direct ancestor to *Homo habilis* may be answered in the future.

One generalization is clear: The very earliest hominid forms emerged in central East Africa long before later hominids, representing *Homo erectus*, migrated north into Europe and east into Asia. Consequently, both Charles Darwin and Louis Leakey are vindicated in light of the growing empirical evidence for the birth of humankind's most remote bipedal ancestors in central East Africa. Of course, models and interpretations of hominid evolution vary among physical anthropologists. And there is no common consensus concerning the classification and interpretation of the growing fossil evidence for hominid evolution. Remaining questions about the origin and emergence of humankind will be answered by the discovery of more fossil hominid specimens and prehistoric stone artifacts in Africa and elsewhere.

Near the famous Hadar site, in Ethiopia, a recent fossil hominid discovery that is 4 million years old could shed more light on the emergence of bipedality (particularly in terms of what the evolving ankle joint contributed to walking upright). Furthermore, at Liang Bua cave, on the Indonesian island of Flores, scientists discovered individual skeletal remains representing a diminutive human species, named *Homo floresiensis*, that lived for thousands of years in isolation from *Homo sapiens*; the age of the bones spans a period from 95,000 to 13,000 years ago. This provocative find illustrates the surprising diversity of early hominids, as well as the enormous influence that geographical isolation has on both the genetic makeup of a remote population and its probable extinction.

The Pongid-Hominid Split

The simplistic three-stage sequence of fossil apes/hominid ancestors/*Homo sapiens*, which was offered at the beginning of the 20th century, has now been necessarily expanded. Present taxonomic schemes account for the ever-growing hominoid and hominid evidence as a result of ongoing research by paleoanthropologists, particularly since the discovery of the "Zinj" skull in 1959. In fact, both the diversity of hominids and the complexity of their evolution is far greater than was imagined in the middle of the 20th century.

The Miocene hominoids represented a large, diversified group of apelike forms that survived and thrived for millions of years throughout the eastern hemisphere. Just several decades ago, fossil hominoid evidence suggested that the split between fossil apes and the earliest hominids had occurred before the end of the Miocene epoch at least 12 million years ago. However, upon careful reexamination of the fossil specimens, all these hominoids were found to be pongidlike rather than hominid-like (suggesting that the pongid-hominid split had occurred much later than was first thought to be the case). A reevaluation of the later Pliocene fossil hominoid evidence places the emergence of protohominids about 5 to 7 million years ago in Africa.

Early hominoid forms ranged from *Proconsul* of Rusinga Island, in Africa, and *Sivapithecus* of the Siwalik Hills, in India and Pakistan (both from the Miocene epoch), to the later *Oreopithecus* of Europe and the huge Pleistocene fossil ape *Gigantopithecus*, of India and China.

About 10 million years ago in central Turkey, the fruit-eating fossil ape *Ankarapithecus meteai* roamed the woodlands long before the pongid-hominid split. Although such forms were once numerous during the Miocene adaptive radiation of hominoid genera and species in Africa and Asia, these fossil apes were becoming extinct during the Plio-Pleistocene time. Insufficient evidence prevents determining which hominoid form is a definite common ancestor of the later African fossil apes and the first protohominids.

The earliest-known hominid, *Ardipithecus ramidus* of Ethiopia, lived about 4.4 million years ago. This form was followed by *Australopithecus anamensis* of Kenya, about 4.2 million years ago, which was later replaced by the emergence of *Australopithecus afarensis* of central East Africa.

The incredible similarities between the human species and the great apes, particularly both the

common chimpanzee (*Pan troglodytes*) and the pygmy chimpanzee or bonobo (*Pan paniscus*), argue for a far more recent pongid-hominid split than was once maintained. With the serious consideration of comparative biochemistry and genetics, as well as molecular dating to determine the evolutionary relationships among different primate species, it became clear that protohominid evolution probably diverged from fossil apelike forms only about 5 to 7 million years ago. If this is true, then the common ancestor shared by apes and the human animal should be found somewhere in central East Africa, the fossil remains being only about 6 million years old.

The various fossil hominoid forms during the Plio-Pleistocene age reflect the diversified habitats of the central East African environment during that time. Through the mechanisms of genetic variation and natural selection (including sexual selection), hominoid populations in a variegated environment gave rise to the pongid-hominid split, which resulted in the apes remaining primarily quadrupeds, on one hand, and the emergence of quasi-bipedal protohominids, on the other; with the latter forms leaving quadrupedal locomotion behind as they ventured out of the forests and jungles for a more and more terrestrial social life in the open woodlands and on the grassy savannahs. (A recent theory maintains that bipedality emerged among the protohominids while they evolved in the forests and jungles.)

There were probably numerous attempts at bipedalism. For whatever reason or reasons, there was an adaptive, survival and, therefore, a reproductive advantage to becoming more and more bipedal as the protohominids evolved into terrestrial hominids. Although a long, branching, and complex process, the evolution of protohominids paved the way for the appearance of the earliest true hominid forms as bipeds over 4 million years ago, for example, the species *ramidus* and *anamensis*.

Even though they stood erect and walked upright with a bipedal gait, the early hominid forms of central East Africa (including *afarensis* and *habilis*) probably returned to the security of the trees during the night in order to escape ground predators.

Human Evolution

In modern physical anthropology, the *habilis-erectus-sapiens* sequence is now well documented in the fossil hominid record, although this history is far

more complex than was once maintained. Furthermore, there is no common consensus concerning the taxonomy of the early hominids, and no doubt additional species will be found. Nevertheless, for over 2 million years, human evolution shows an increase in the size and complexity of the brain, a reduction in the size of the face and teeth, and an ever-increasing reliance on cultural adaptations (especially symbolic language, manufactured stone technology, and social patterns of cooperative behavior). Although speech, consciousness, and behavior are not preserved in the fossil record, they may be inferred from osteological and archaeological remains.

Like other emerging groups of animals, the early hominids underwent adaptive radiation. To date, over 500 fossil hominid specimens have been found from sites in Africa. This diversity among the early and then later australopithecines resulted in many genera and species. No doubt, many other forms of early and later australopithecines will be found as future paleoanthropologists continue searching for fossil evidence at sites ranging from 1 to 5 million years ago in Africa.

About 2.8 million years ago, a population of *Australopithecus africanus* inhabited subtropical woodlands in South Africa. These bipedal hominid individuals had a small brain, long arms, and short legs; they may have coexisted with *Australopithecus afarensis*, with the probability that both species once shared a common ancestor. This hominid evidence suggests that perhaps the transition from *africanus* to *habilis* may have taken place in South Africa (rather than in central East Africa), followed by the *habilis* species migrating northward.

Within this diversity of australopithecines, it is the bigger-brained, implement-making, and wider-ranging *Homo habilis* that was successful in terms of adapting, surviving, and reproducing over 2 million years ago. Other hominid forms became extinct (for example, *Australopithecus aethiopicus*, *Australopithecus africanus*, *Australopithecus boisei*, and *Australopithecus robustus*). Because of its superior brain and Paleolithic culture, *Homo habilis* not only survived, but, more important, it gave rise to the next stage of hominid evolution, *Homo erectus*, about 2 million years ago. This transition was not sudden, for the *habilis* and *erectus* phases overlapped in central East Africa.

The emergence of *Homo erectus* from *Homo habilis* represented a major change both in the biological

and sociocultural advances in hominid evolution. Compared to *habilis*, *erectus* was taller and had a larger brain. It even migrated both north into Europe and east into Asia, although populations of *erectus* remained in Africa. For almost 2 million years, *erectus* survived and thrived throughout the eastern hemisphere. Its culture consisted primarily of stone Acheulean bifacial hand axes, along with cleavers and scrapers in Africa and stone chopper/chopping implements in Asia. From an evolutionary viewpoint, *Homo erectus* represented a long and successful stasis in hominid biocultural evolution. Even so, recent fossil hominid evidence suggests that the *erectus* stage of human evolution may actually represent a diversity of forms (perhaps even different species).

With the extinction of all other hominid genera, *Homo erectus* is directly ancestral to *Homo sapiens*. Before the emergence of the human species, the average hominid brain evolved slowly for about 2 million years, from about 630 cc in *habilis* to about 900 cc in *erectus*. Then, both the size and complexity of the hominid brain evolved faster, reaching an average of 1,400 cc in *sapiens* today. With the appearance of *Homo sapiens*, the human species manifested far greater self-consciousness, along with the emergence of symbolic language as articulate speech (although a crude form of symbolic speech as protolanguage may be over 1 million years old).

About 400,000 years ago, with the extinction of *Homo erectus*, the archaic *Homo sapiens* form first appeared (this stage of hominid evolution probably emerged in Africa before spreading north into Europe and east into Asia). In South Africa, about 120,000 years ago, an early member of the human species left fossil footprints at Langebaan Lagoon and cultural remains (ashes, mussel shells, and animal bones) in caves at Klasies River Mouth. This evidence suggests that South Africa may have been the birthplace of modern *Homo sapiens*, or at least a species anatomically like humans.

The later *Homo sapiens neandertalensis* populations represent a complex and elusive phase of human evolution, showing great regional variation until about 35,000 years ago. They were hunters, gatherers, and scavengers who occupied caves and used fire. More advanced both biologically and culturally, the classic Neandertal people had a modern cranial capacity and the far more sophisticated culture of the Mousterian tradition, including the deliberate burial of their dead with ritual (suggesting the emergence of

magico-religious beliefs and practices). In some areas of the eastern hemisphere, the Neandertals were contemporary with the even more advanced Cro-Magnon people, with the two forms intermittently occupying the same sites. Apparently, the two subspecies seldom, if ever, mixed their gene pools. Any *neandertalensis-sapiens* overlap was relatively brief. For whatever reason or reasons, the Neandertals would eventually disappear, thereby setting the stage for the success of the Cro-Magnon people as *Homo sapiens sapiens* (early phase).

The Cro-Magnons had even greater self-consciousness, and it was expressed in the creative explosion of tools (for example, blades and burins) and works of art (for example, stone sculptures and, in particular, the painted cave murals at Altamira in Spain and Lascaux in France). Surely, the Cro-Magnon people were far more sophisticated than the Neandertals in terms of thought and behavior. The Cro-Magnons built shelters and had articulate speech; perhaps their greater social intelligence and advanced symbolic language (rather than genetic makeup) separated them from the rapidly vanishing Neandertals. Moreover, the Cro-Magnon people are directly related to *Homo sapiens sapiens* (present phase); that is, they were the immediate ancestors to modern humans.

Following the most recent Ice Age, *Homo sapiens sapiens* has been enormously successful in adapting to different environments around the world as a result of the evolution of culture, especially accelerating advances in science and technology. Yet despite sociocultural diversity, the human species has remained a biological unit on this planet. At this present stage of hominid evolution, through genetic engineering, the human animal is becoming more and more capable of directing the further development of itself as well as the ongoing evolution of other plant and animal species. One may argue that the human species, as the bipedal ape or third chimpanzee, is becoming the cosmic primate. In fact, humankind's self-imposed destiny may require adapting to habitats on other worlds.

At present, several different interpretations of human evolution are possible. For example, conflicting phylogenetic models depicting the relationship between humankind's common hominid ancestor and later hominid forms are presented by Donald C. Johanson and Richard Leakey. One may even argue that each of the major phases of hominization first

appeared in Africa. Yet the earliest making of fire and the origin of symbolic language as articulate speech may always elude the paleoanthropologists. For the rigorous evolutionist, explaining the long and complex emergence of the human species (strictly in terms of a naturalistic worldview) requires no appeal to a divine plan or predetermined direction or necessary end goal.

The human species is not nailed to this planet, but it is tied to life on earth through genetic evolution. Likewise, the human animal is always subject to the threat of extinction, which remains a possibility in light of the fact that most of the billions of species that have inhabited this planet are now extinct. Ironically, the evolutionary success of the human species in terms of sheer numbers may well be the cause of its future demise (in sharp contrast to humankind's population explosion, the small wandering bands of our earliest bipedal ancestors had been successful for millions of years). Furthermore, there is the ever-increasing possibility that the human species' modern technology (which represents extraordinary progress from the manuports and eoliths of remote hominid ancestors to the stealth jet and space shuttle of today) will in the future either destroy or supersede humankind as now known. Or, in time, the human species may give rise to a new form of life.

In short, hominid evolution has been about a 5-million-year journey from our earliest ancestral form in central East Africa to the self-reflective global species that it represents today. As a result of ongoing research in paleoanthropology, a much clearer and more complete picture of human evolution will emerge in light of the discovery and interpretation of additional fossils and artifacts. With the use of sophisticated computer simulations, future paleoanthropologists will provide science with a better understanding of and deeper appreciation for the emergence of the human species.

Hominid evolution has been a far more complex process than was thought just a few decades ago. The growing fossil evidence clearly documents the past existence of many hominid forms. Yet only one species has been successful, and this form represents the present biological unity of humankind.

About 3.6 million years separate the fossil hominid tracks at Laetoli from Neil Armstrong's footprints on the moon. Overcoming incredible odds and the threats of extinction, hominid evolution has been a

remarkable success story. No doubt, in the distant future, humankind's descendants will leave both their bipedal impressions and cultural achievements on the surfaces of remote planets.

EVOLUTION EDUCATION CONTROVERSY

Eighty years after the famous Scopes "Monkey Trial" in 1925, in 2005, American education received a surprise as the controversy over evolution in textbooks was revived. This time it was not in the "Bible Belt" state of Tennessee, but in progressive Pennsylvania. Among religious conservatives, the

"theory of intelligent design" has grown up, asserting that the universe was simply too complex to emerge from a single, atypical cosmic big bang. (In fact, intelligent design is itself only a modern fugue on the far older theory of a first cause for the universe, as taught by generations of priests of the Roman Catholic Jesuits, or Society of Jesus.) Intelligent design, while gaining many adherents, has never actually been considered as part of any school biology curriculum.

However, things changed dramatically in November 2004. In that month, the school board in rural Dover, Pennsylvania, voted that biology teachers had to inform their classes that "evolution may not, after all, explain how we all got here," explained ABC News. The decision of the school board made national news, rapidly thrusting the controversy over evolution versus intelligent design into the headlines as it has not been since John Thomas Scopes was brought to trial in Tennessee for teaching evolution.

Immediately, the issue became a cause with both the religious right, whose contribution was important to President George W. Bush's 2004 presidential campaign, and liberal activist groups like the American Civil Liberties Union (ACLU). The ACLU paid prime attention to the developing case in Dover, providing massive legal support to fight the school board's decision. Indeed, into early 2005, the controversy was unresolved; similar scenarios were also being played out in the states of Georgia and Ohio.

FUTUROLOGY

There have been few "students" of the future with the impact of Alvin and Heidi Toffler, whose previous works *Future Shock*, *The Third Wave*, and *Powershift* focused the attention of Americans on serious consideration of the future. Their most recent book, *War and Anti-War*, brought attention

to a new aspect of the future: the shape and conduct of warfare. In their book, published in 1993, they foresaw the development of electronic warfare, as we see today in the use of Predator drone aircraft.

The Tofflers also wrote of the rise of religious extremism, which in February 1993 saw the first terrorist bombing of New York's World Trade Center. "A minority of Islamic extremists," they warned, "conjure up fantasies of a New Crusade, with the entire Muslim world united in a jihad, or Holy War, against Judeo-Christianity." Even more, they foresaw the dangers of nuclear proliferation. They wrote, "prior to the Gulf War [of 1991], the IAEA (International Atomic Energy Agency) used the equivalent of only 42 full-time inspectors to check on 1,000 declared nuclear energy plants around the world." That figure did not take into account clandestine, or hidden, ones.

Even more, *War and Anti-War* focused on what is known today as electronic warfare or information warfare. Information warfare involves the use of computers to not only plan a country's military campaigns—but also to frustrate an enemy's "cyber-warriors," with such things as "Trojan Horses" and other computer weapons. Indeed, both the United States and the People's Republic of China today emphasize information warfare as a weapon that may indeed one day decide the outcome of a battle. In 1993, the Tofflers wrote how "with only a limited grasp of its implications, nations everywhere are preparing, as best they can, to exploit knowledge-intensivity."

Yet with some of the new technologies have come new risks. The Tofflers wrote of lasers being used to guide bombs and missiles, a significant part of the deadly accuracy of the bombardments that preceded the invasions of Afghanistan in 2001 and Iraq in 2003. However, in the new field of nonlethal weaponry that has developed since the Tofflers' book, lasers are now seen as battlefield weapons that can be used against enemy troops to not only disorient them but blind them as well. As with all else in modern weaponry, including biological weapons, there is a fear that such weapons may reach the hands of terrorists. In the waning months of 2004, there were several reported incidents of laser beams being directed into the eyes of civilian airline pilots. There is

evidence that terrorists have explored using lasers as weapons, though there is no specific intelligence indicating al Qaeda or other groups might use lasers in the United States.

— John F. Murphy Jr.

MONOGENESIS VERSUS POLYGENESIS

The theories of monogenesis and polygenesis set forth opposite theories of how the human race evolved. Those who believe in monogenesis say that all humans share the same origin. Polygenesis asserts that at least some of the races had a separate origin. It maintains that different races have different origins, different characteristics, and different histories.

Monogenesis was widely adhered to in Christian Europe through most of its history. This was mainly because the Bible was believed to say that all humans descended from Adam and Eve, giving them all a common origin. Belief in polygenesis became widespread in the United States during the middle of the 19th century. This was in part because it was becoming difficult to reconcile the biblical account with new scientific evidence.

The early polygenists relied mainly on scientific evidence and ignored biblical arguments that the monogenists used. For a while, the pendulum swung toward belief in polygenesis. Some believe that polygenesis was used to further racism in the United States. Charles Darwin was a believer in monogenesis and believed that polygenesis was just an excuse for racism. When interest in polygenesis was at its height in the United States, some of the leading American polygenists shifted the focus of their beliefs. Rather than concentrating on proving that different races had different origins, they began to focus their efforts on proving that the then current differences in the races would continue unchanged.

The theories of monogenesis and polygenesis are also debated by linguists trying to determine

the origin of languages. Approximately 5,000 languages are spoken in the world today. Did all of those languages spring from one original language? Or did many languages develop in many different locations? Linguists analyze languages to find systematic differences and similarities. They believe that those with similar structures may have evolved from a common ancestor. There is even debate among linguists about whether or not certain languages should be grouped together in families. Linguists divide into the lumpers and the splitters. Lumpers believe that there are only approximately two dozen languages. Splitters believe that there are many times that number of basic groupings.

Joseph Greenberg of Stanford University is convinced that the original language developed in Africa among early *Homo sapiens*. He believes that the original language, which he calls the Mother Tongue, diverged eventually over time into the several thousand languages spoken today.

So the debate goes on. No one has proven conclusively that either monogenesis or polygenesis is correct.

— Pat McCarthy

IAN TATTERSALL

Paleontologist, evolutionary biologist, and primate behaviorist Ian Tattersall is curator of anthropology at the American Museum of Natural History in New York and adjunct professor of anthropology at the City University of New York. Tattersall's biography is as diverse and varied as his academic interests. He was born in England but grew up in East Africa and received his professional training at Cambridge (archaeology and anthropology) and at Yale (geology and vertebrate paleontology). His fieldwork has taken him to countries such as Madagascar, Vietnam, Surinam, Yemen, and Mauritius.

Tattersall has focused on two main areas of research, in which he has achieved international

fame: the analysis of the human fossil record, and the study of the ecology and systematics of the lemurs of Madagascar. His many books, including *Becoming Human: Evolution and Human Uniqueness* (1999) and *Extinct Humans* (2001), have popularized scientific findings on evolution and primates for a general readership. His studies have proved extremely readable, yet other scholars in the field have criticized them for their lack of academic references and sustained evidence.

Source: Denis Finnin/AMNH.

Tattersall argues that in the evolutionary process, there is "continual evolutionary experimentation, with constant origins of new species, triage among those species by competition, and the extinction of the unfortunate." He also asserts that humans owe much to chance and opposes the theory of modern evolutionary synthesis, which brings together Darwinian evolution and the laws of Gregor Mendel. Tattersall has revised the straight-line progression of the human "family tree," which would take the human race from the apelike *australopithecines* to the mysterious *Homo habilis* to the legendary Neandertals and culminate in the superior *Homo sapiens*. According to his theory, many different types of extinct species have coexisted during the evolutionary process.

Tattersall has identified the Cro-Magnons as the ancestors of humans, claiming that the Neandertals were replaced by them. The defining feature, which differentiates the two hominids and which makes humans unique, was the development of symbolic thought that is clearly shown in the elegant artworks found in the Cro-Magnon caves. "Art, symbols, music, notation, language, feelings of mystery, mastery of diverse materials and sheer

cleverness: all these attributes, and more, were foreign to the Neandertals and are native to us," Tattersall concluded in *Becoming Human*. Yet, in spite of his celebration of human abilities, Tattersall seems to have doubts about the potential of contemporary humankind for further evolution: "Everything we know about evolution suggests that to get true innovation, you need small, isolated populations, which is now unthinkable."

— Luca Prono

EVOLUTION, MODELS OF

Several major models have been used to represent organic evolution on earth. These models include the arc, line, spiral, circle, pyramid, and tree or bush or coral of life forms throughout biological history.

Aristotle (384–322 BCE), the father of biology, including morphology and taxonomy, taught that plants and animals represent a hierarchical line of eternally fixed forms. These kinds of life range from the simplest plant to the most complex animal, with our own species, as the only rational being, at the apex of this planetary ladder of the living world. Aristotle's great chain of being, from global minerals to celestial stars, was not an evolutionary interpretation of this universe.

Aristotle's worldview is grounded in the assumption that each type of life has a fixed essence. Consequently, this natural philosophy contributed to an antievolutionary view of organic history for nearly 2,000 years.

Carolus Linnaeus (1707–1778), the father of modern taxonomy, classified the living world into groups of similar life forms (for example, the primate order includes our species, apes, monkeys, and prosimians). Linnaeus was not an evolutionist, although he did admit that a species may produce varieties of itself.

As the first serious evolutionist, Lamarck (1744–1829) interpreted organic history as an escalator of evolving species. He wrote that the human being has evolved from the chimpanzee in Africa and the orangutan in Asia. With little empirical evidence and no explanatory mechanism that could be tested, Lamarck was unable to convince other naturalists that species are mutable and evolve throughout vast periods of time.

Charles Darwin (1809–1882) wrote about the evolving tree of life in order to represent the branching out of successive species over eons of organic time. To also include the fact that plant and animal forms have become extinct throughout biological history, he preferred to interpret organic evolution as the coral of life. Darwin's empirical evidence, from paleontology to morphology, and explanatory mechanism of natural selection convinced several important naturalists that species either evolve or become extinct over time. His own sketch of evolving species illustrates the principle of divergence, thereby challenging all straight-line interpretations of organic history.

Ernst Haeckel (1834–1919) was the first evolutionist to draw a detailed picture of the tree of life. In fact, he drew several illustrations to demonstrate the historical relationships among groups of species as a branching tree of organic evolution. These illustrations may be seen in his home Villa Medusa, now a museum in Jena, Germany.

Several thinkers have interpreted evolving nature as a circle. Herbert Spencer (1820–1903) saw the universe in general and earth history in particular as a returning circle, each cycle representing the three basic stages of evolution, equilibrium, and devolution; yet each cycle would be different in its content.

However, Friedrich Nietzsche (1844–1900) held that given enough time, the identical cosmic cycle would return. In fact, for him, this same cycle would repeat itself forever. Nietzsche's awesome idea of the eternal recurrence of this same universe is the quintessential assumption of his metaphysical position.

Critical of Darwinian mechanistic materialism, Henri Bergson (1859–1941) argued that a vital force is necessary to account for the pervasive creativity throughout organic evolution. For him, this vital force has caused the creative divergence of plants, insects, and animals within biological history. In his interpretation of reality, our species now represents the apex of organic evolution in terms of consciousness. Yet, in the final analysis, Bergsonian philosophy gives preference to metaphysics and intuition rather than science and reason.

Although influenced by Henri Bergson, the geopaleontologist and Jesuit priest Pierre Teilhard de Chardin (1881–1955) emphasized global convergence rather than planetary divergence. Teilhard saw earth history in terms of three successive circles: the inorganic geosphere, the organic biosphere, and the human noosphere. Seeing things within the framework of a

spiraling and involuting pyramid, he believed that the further evolution of our species on planet earth will result in a mystical unity of humankind with God. Teilhard referred to this final end goal for our species as the “omega point.”

Today, most neo-Darwinians reject both teleology and essentialism. They interpret organic evolution and our species within a strictly naturalistic framework. Earlier models of evolution have been modified in light of the growing fossil and genetic evidence, as well as the use of computers to understand and appreciate the patterns in biological history. Ongoing inquiry will generate new models of organic evolution.

One may speak of emerging teleology as scientists genetically engineer new life forms and, through human intervention, more and more direct the continuous evolution of our own species and others. Furthermore, empirical evidence documenting exobiology and exoevolution would result in a conceptual revolution concerning interpreting the place of life and humankind within this dynamic universe.

EVOLUTION, MOLECULAR

Theories of molecular evolution try to explain the natural history of deoxyribonucleic acid (DNA), which is the material carrier of genetic information.

Evolutionarily relevant variations between organisms must be implemented in the biochemical structure of DNA sequences. Otherwise, those variations

Source: © iStockphoto/Andrei Tchernov.

would not be genetically transmitted from an organism to its offspring, so they would disappear from nature after one generation. Molecular evolution is thus the foundation of evolution on all higher levels of biological organization, like the organism, the population, or the species.

After the famous discovery of the double-helical structure of DNA by James D. Watson and Francis H. Crick in 1953, it was known that genetic information is stored in sequences of four DNA building blocks, the nucleotides. That parts of the linear structure of DNA store genetic information means that those parts can instruct the biosynthesis of proteins, which are the most important macromolecules for cellular metabolism. More concretely, the specific succession of nucleotides can encode the primary structure of a protein, that is, the linear sequence of amino acids linked by peptide bonds. In the information bearing parts of DNA, three nucleotides (a codon) encode one amino acid. A gene is the informational unity the function of which is to encode the complete primary structure of a protein. The set of rules that relate each of the 64 possible codons (one has to take the number of nucleotides, which is four, to the power of the number of nucleotides in a codon, which is three) to an amino acid residue constitutes the genetic code. Those rules cannot be deduced from the laws of biochemistry alone. The molecular evolutionist must also reconstruct the historical and contingent physico-chemical context in which the genetic code originated.

The biological disciplines that are involved in discovering the laws of molecular evolution and in reconstructing its course are, above all, biochemistry, molecular and population genetics, systematics, and general evolutionary theory.

Biochemistry and molecular genetics analyze the material structures and the physico-chemical mechanisms that realize the storage, replication, variation, transmission, and reading of genetic information. The success of this project is evident from the enormous technical progress that was made during the last 30 years in the development of genetic engineering.

Population genetics studies the evolutionary dynamics by which the relative frequency of genes changes with time in populations of organisms. Mathematical models were

developed that describe different types of evolutionary dynamics in a more and more realistic way. These models can be tested against empirical data gathered by systematic analyses of wild-living populations.

Systematics classifies the rich variety of species, which lived and live on Earth, in order to reconstruct their evolutionary relationships in so-called “phylogenetic trees.” Such a tree shows graphically how some species, with which we are concerned, are related to each other by placing their common ancestor at its root and by illustrating the separation of a new species with a branching point. Finally, the species in question are to be found at the top of the resulting branches. Before the advent of automated DNA-sequencing techniques, morphological descriptions were the most important data on which phylogenetic trees were based. Nowadays, molecular data of DNA sequences are of equal importance for the reconstruction of natural history.

General evolutionary theory tries to synthesize the insights of the before-mentioned biological disciplines in an all-embracing picture of molecular evolution. This integration is to be accomplished by discovering the causal mechanisms that can explain the facts of natural history.

What mechanisms are responsible for molecular evolution? Of course, the answer that first comes to mind is natural selection, the evolutionary mechanism that stands in the center of Charles Darwin’s research on the origin of species. His theory can be applied to the molecular level, if we remember that the differences between individual organisms and therefore also between species are caused by differences in their genetic material, which are, in turn, caused by mutations in the nucleotide sequences of their DNA.

Since those mutations are inherited by offspring, fitness as the measure for the evolutionary success of an organism can be redefined on the molecular level as the replication rate of its genes in the gene pool of its population. The struggle for life described by Darwin is thus the struggle of genes to raise the number of their copies in the next generation. The more copies of a DNA sequence that are successfully transmitted to offspring, the fitter it is.

But there is another theory that claims also to contribute important insights to the explanation of the course of molecular evolution. This claim is laid by the neutral theory of molecular evolution, which the Japanese population geneticist Motoo Kimura has developed since the 1960s. He postulates that most genetically transmitted mutations are selectively neutral; they do not have any positive or negative consequence on the fitness of the organism in which they occur. The spread of neutral mutations in the gene pool of a population, called “genetic drift,” has then nothing to do with natural selection. It is a process that follows, from the perspective of natural selection, a completely random course.

Today, even staunch Darwinians accept that genetic drift constitutes an important mechanism that is effective in natural history. On the other hand, it seems to be also clear that randomness cannot explain everything in evolution. Kimura’s neutral theory does not completely replace Darwin’s selection theory, but it describes an explanatory scheme that supplements traditional Darwinian reasoning. In concrete cases of explaining a molecular evolutionary process that happened between kindred species, it is often very difficult—and perhaps impossible—to decide which of the two theories proves to be right.

How difficult it is to develop a general evolutionary theory on the molecular level will be clear after one has realized that it has to address not only the evolution of DNA. Molecular evolution also encompasses the evolution of precursors of DNA and, last but not least, the origin of the first material carrier of genetic information. Since the existence of genetic information presupposes the existence of a genetic code, the origin of the latter belongs to the main problems of research into molecular evolution, too.

EVOLUTION, ORGANIC

Evolution, in the modern sense, refers to changes in the genetic composition of populations over time and is the result of natural selection and/or genetic drift acting on population variation. In this Darwinian paradigm, species may change or split into more than one species (speciation). All extant species are descendants of a common ancestor (descent with modification). Definition of the term in this framework encompasses the gene-frequency changes of population microevolution, anagenetic changes within a lineage, cladogenesis, and the appearance of evolutionary novelties. The present diversity of organisms was produced by change within species (anagenesis) and splitting of species (cladogenesis) through geological time, in contrast to the explanations offered by separate creation and Lamarckian transformism. The former denies both the mutability and common ancestry of species, and the latter invokes change within species but denies the splitting and common ancestry of species. Historically, the term *evolution* was also used to describe development of the embryo and in the theory of embryonic recapitulation.

Evolution is a process that occurs in populations rather than in individuals: The genetic composition of a population changes, but that of the individual does not. Evolution occurs in populations by changes in the frequencies of alleles and genotypes. The changes at the genetic level are observed in the phenotypes of individuals (e.g., protein structure, individual morphology, behavior).

Ernst Mayr identifies five major postulates that form the foundation of the Darwinian paradigm: (1) organisms change through time, (2) all organisms have a common ancestor, (3) species multiply by

Figure 1 Thoday and Gibson conducted a selection experiment on a number of sternopleural chaetae (stout hairs, bristles) in *D. melanogaster*. The histograms depict distribution curves for each generation S1-S12. Green is progeny of low number females and orange is progeny of high number females. Disruptive selection caused the high chaetae group to diverge from the low chaetae group.

splitting or budding, (4) gradualism, and (5) natural selection. It should be pointed out that the Darwinian concept of gradualism is not that evolutionary change is necessarily slow and steady. Rather, it is that evolution does not occur by saltations, the results of macromutations that render offspring reproductively isolated from the parental generation, *sensu* the writings of Richard Goldschmidt.

Evidence for Evolution

Matt Ridley points out that two fundamental questions need to be answered to demonstrate evolution. Do populations and species change through time? And do living organisms share a common ancestor? The evidence used to answer these questions in the affirmative comes from a number of sources, including observation of evolution on a small scale, the presence of extensive variation among populations and subspecies, homology, adaptive radiation, and the fossil record.

Evolution “on a small scale,” over a number of generations rather than over millions of years, has been achieved under domestic and experimental conditions and observed in the wild. The origin and development of domestic breeds of animals and plants has been a topic of interest to anthropologists and clearly demonstrates that species change. In *On the Origin of Species* (1859), Charles Darwin discusses the production of domestic breeds as the result of “accumulative selection” by humans and points out that breeders and horticulturalists intentionally modify breeds within a human lifetime. He particularly concentrates on the origin of pigeon breeds. Darwin also addresses “unconscious selection,” in which a breed is altered simply by breeding the “best” individuals (for example, the English pointer dog). In both techniques, the breeder is allowing only those individuals with extreme values of a particular character to produce offspring during each consecutive generation (the “traditional breeder’s approach”). This shifts the mean value for the selected characteristic during successive generations in the descendants: The breeder is applying directional selection to the particular trait of interest (the somewhat unfortunate term “artificial selection” is often applied to this methodology, which could be misconstrued). Darwin expands upon this discussion in *The Variation of Animals and Plants Under Domestication* (1883) and states that domestication is a gigantic experiment in selection. Modern

discussions of the principles and results of plant and animal breeding are couched in terms of genetics.

In an experimental context, both the traditional breeders' approach and natural selection in a controlled environment have been employed to demonstrate change in populations. Well-known examples of the former have focused on disruptive selection on the number of sternopleural chaetae (stout hairs) in the fly, *Drosophila melanogaster*. These experiments not only sought to demonstrate that change in mean population chaetal number would result from differential reproduction but also tested whether disruptive selection could overwhelm the results of gene flow—a central issue in sympatric and parapatric speciation models. The general approach was to allow flies with low chaetal number and flies with high chaetal number to breed, but not allow breeding by those with intermediate numbers. The results consistently showed shifts in mean population numbers over time. The same approach was employed in a behavioral context by J. C. Tryon, a pioneer of behavioral genetics, in his famous experiment on maze-running ability in rats. Later applications include the work of Rodriguez-Ramilo and associates on the effects of inbreeding and selection on *D. melanogaster*.

In experiments that employ natural selection in a controlled environment, subjects are exposed to a predetermined environmental regimen for one or more generations, but the experimenter does not directly determine which individuals breed. D. N. Reznick and associates used this approach in field experiments in which guppies were moved from areas where they were subject to predation by cichlid fishes to sites where they were not; the descendants of guppies from sites with less predation matured later and at a larger size than descendants of those from high predation sites. The approach is particularly valuable for the study of niche dimensions, range limits, and character displacement.

Demonstration of the occurrence of evolution in the wild often falls within the discipline termed *ecological genetics*, a combination of naturalistic observation, experimentation in the field, and the use of laboratory genetics. Ecological genetics seeks to establish that change occurs within populations and species, to demonstrate that there is a hereditary basis to phenotypic variation, and to identify the agent of change. The work of J. H. Gerould on color polymorphism in caterpillars is cited as an early example.

Figure 2 Industrial melanics from a variety of moth genera. The typical variety of the peppered moth is in the upper left (1) and the *carbonaria* form (2) is below it.

Source: Plate 5.6 (p. 62) from *The Evolution of Melanism* by Kettlewell, B. (1973). By permission of Oxford University Press.

A common methodology employs the following components: (1) observations and collections made to establish that distinct phenotypes (generally of a trait that manifests clear polymorphism) are found in the wild, (2) establishing that there is a change in the proportions of the phenotypes over time or geographic distance, (3) determination that there is a genetic basis to the various phenotypes, and (4) identification of the agent that is responsible for altering the frequencies of phenotypes and genotypes. The latter step is often the most difficult, because the occurrence of a feature may be influenced by more than one process. In *Ecological Genetics*, Edmund B.

Figure 3 The frequencies of *carbonaria* (blue areas) and *typica* (green areas) in Britain. Shaded segments represent the *insularia* variety, which is not discussed in this entry. There is a strong correlation between pollution levels and frequency of *carbonaria*: High frequencies were close to, or east of, polluted industrial districts; in contrast, Scotland and southwest England show virtually no *carbonaria*.

Ford synthesizes the extensive literature on shell polymorphism in *Cepaea nemoralis*, chromosome polymorphisms in *Drosophila*, mimetic polymorphism in butterflies such as *Papilio dardanus*, and industrial melanism.

Industrial melanism is generally cited in discussions of evolution demonstrated on a small scale. A classic example has been that of wing and body color polymorphism in the English peppered moth, *Biston betularia*. Michael Majerus states that melanism occurs whenever there is a pervasive darkening of the ground color or patterning of an organism. The term *industrial melanism* applies to darkening as a result of industrial pollution of the environment. The

first-known melanic specimen of the peppered moth was captured in 1848, in Manchester, and melanics rapidly increased to 98% to 99% of the population by 1895 to 1898. The books of Ford, Bernard Kettlewell, and Majerus summarize literature on the phenomenon dating back to 1864. It is often held that the origin of the melanic *carbonaria* was a single point mutation in the region around Manchester, with subsequent migration to other areas, but Majerus indicates that there may have been more than one mutational event. Early explanation of the occurrence of melanism invoked Lamarckian transformism. A mutation pressure explanation was advanced by J. W. H. Harrison in 1928. He argued that melanism was induced in adults as a consequence of larvae feeding on leaves contaminated with mutagens that increased the mutation rate of genes associated with melanin production. However, it has never been confirmed that the influence of environmental stimuli during development can induce melanism in adult Lepidoptera.

The Darwinian natural selection explanation replaced those of the inheritance of acquired characteristics and mutation pressure. The primary explanation of the geographic spread, and numerical increase of *carbonaria* became that of selective advantage of the melanic form over that of the lighter *typica* in areas of industrial air pollution, because of camouflage from insectivorous birds. The

occurrence of industrial melanism in Lepidoptera gave rise to a series of elegant studies of *Biston betularia*, summarized by Ford, Kettlewell, and Majerus, and Kettlewell's work had a significant impact on the acceptance of natural selection as an agent responsible for evolution. His investigations included a controlled experiment on bird predation on moths in an aviary to construct quantitative degrees of camouflage effectiveness, field experiments in polluted (Christopher Cadbury Bird Reserve, Birmingham) and unpolluted (Deanend Wood, Dorset) localities, and surveys of peppered-moth frequencies throughout Britain. The fieldwork included mark-recapture, studies to determine whether moths released in

early morning were still at the release point later in the day, and (with Niko Tinbergen) filming of actual bird predation on moths. Kettlewell concluded that differential selective predation by birds was responsible for differences in the relative frequencies of *typica* and *carbonaria* in areas that had become polluted.

It has been realized that the classic exposition of natural selection on *Biston betularia* is too simple, in part because camouflage and predation do not seem to be important in maintaining melanism in some other taxa. A variety of workers have studied industrial melanism in the ensuing decades since Kettlewell's landmark work. The term industrial melanism is now applied to taxa such as the two-spot ladybird and the pale brindled beauty moth, without the implication that predation is responsible for maintaining the polymorphism. Kettlewell himself pointed out that melanism affects many aspects of an organism's life, including behavior, sexual selection, temperature tolerance, and physiology of pigment production; natural selection could potentially affect the moth population through any of these features, among others. Publications by Bruce R. Grant and Majerus review many of the major criticisms, including that large numbers of released moths produced artificially high prey densities and may have attracted birds; moths settled on tree trunks, but it is unclear whether this is a natural hiding place for *B. betularia*; moths released during daylight hours do not behave normally; a combination of lab-raised and wild-caught moths were used; there are differences between human and bird vision; and there was no evidence that typicals and melanic forms prefer to rest on different backgrounds—contra Kettlewell's barrel experiments. However, these authors conclude that such shortcomings do not jeopardize the principal conclusions that the intensity of bird predation varies according to habitat and that industrial melanism in the peppered moth is a valid example of natural selection and evolution in the wild. There was a solid correlation between pollution levels and the frequency of the melanic form. Kettlewell compared the relative success of the morphs on the same parts of trees in different areas (not different parts of trees in the same area), and he showed that moths that were most conspicuous to humans were also eaten first by birds. Kettlewell's conclusions are bolstered by recent studies of predation on male mosquitofish by Lisa Horth.

Geographic variation in intraspecific phenotypes and proportions of genotypes provides evidence for evolution. If a species is studied in the wild, it will generally be found that there are phenotypic variants in different geographic areas. Often, these variants are designated as subspecies of the species; variation is often so extensive that small differences in samples of populations have been used to assign subspecific rank, and some have argued that the subspecies category has been overutilized. Examples of variation within the primates include the geographic variants found within sub-Saharan vervet monkeys (*Cercopithecus aethiops*), South American white-fronted capuchins (*Cebus albifrons*), tufted capuchins (*Cebus apella*) and common squirrel monkeys (*Saimiri sciureus*), and the northern greater galago (*Otolemur garnetti*). Interpopulation variability is often readily interpreted in terms of environmental factors to which each population has adapted, as in the cases of *Peromyscus* mouse populations to substrate color and cyanogenic clover (*Trifolium repens*) to probability of frost. The latter also illustrates that interpopulation variation can be distributed in the form of a cline, a gradual change in a phenotypic character or genotypic along a geographic transect. In humans, there is a cline in the frequency of B type blood across Eurasia. A cline may be formed by interbreeding between formerly isolated populations or by geographic variation in selection pressures on a character. Descent from a common ancestor and subsequent local evolution are the most logical and parsimonious explanations for geographical variants. Special creation and transformism would have to explain each local variant as having a separate origin. Explanation by Lamarckian transformism would be particularly hard to envision, as it would necessitate separate origin by spontaneous generation for each population, followed by the inheritance of acquired characteristics that would make populations separated by hundreds of miles sufficiently different to be distinguished only at the subspecies level.

Powerful evidence from geographic variation comes from ring species, in which there is an almost continuous set of intermediates (cline) between two sympatric species, and the intermediates are arranged in a ring. The set of intermediates between the lesser black-backed gull (*Larus fuscus*) and herring gull (*L. argentatus*) is distributed around the North Pole. As one moves along the ring, there is only one species present in any local area. However, there are

Figure 4a Phylogeny of Darwin's finches based on microsatellite length variation

reproductively and ecologically separate species where the two end points of the ring meet in Europe. Mayr terms this “speciation by distance.” Ring species demonstrate that intraspecific variation can be great enough to make two species and that there is a continuum from interindividual to interspecific variation. Recent research on greenish warblers (*Phylloscopus trochiloides*) by Darren E. Irwin and colleagues, using amplified fragment length polymorphism markers, provides evidence that speciation by distance can produce distinct species despite gene flow along the ring.

Homology is the possession by two or more species of a trait derived, with or without modification, from a common ancestor. Gunter P. Wagner terms it the central concept of comparative morphology. It is also robust evidence for evolution, for structures are homologous because of common descent, not because of close similarity in function. Wagner explains that homologous structures (homologs) are those that have been acquired only once in the history of a group of organisms possessing the character; those features of a development system that cause restriction in phenotypic consequences of genetic variation are important in determining that features are homologs. Well-known examples are the pentadactyl hand of a primate and the pentadactyl wing of a bat: They both possess five digits because of descent from a common ancestor, not because of close similarity in function.

Wagner also points out that the study of homologs is the basis for the reconstruction of phylogenetic history by morphological methods. This has historically been true in the study of adaptive radiations before the advent of molecular phylogenetic approaches. An adaptive radiation occurs when a single ancestral species diversifies into a large number of descendant species that occupy a variety of ecological niches and differ in traits used to exploit those differing niches. Articles in *Molecular Evolution and Adaptive Radiation* (1997), edited by Thomas J. Givinish and Kenneth J. Sytsma, give alternate definitions. Well-known examples include the radiations of placental and marsupial mammals, Hawaiian silversword plants, African cichlid fishes, and Caribbean *Anolis* lizards. All 14 species of Galapagos finches share finch homologies and are members of the single subfamily Emberizinae of the finch family Fringillidae. In the even more diverse radiation of Hawaiian honeycreepers, all species share finch

homologies. Although beak size is a continuously varying character governed by both genetic and environmental factors, Galapagos finch and Hawaiian honeycreeper species manifest beaks adapted to particular foraging strategies and diverse niches.

The evidence for evolution that is most often cited is from the fossil record. Four aspects of the fossil record are particularly important: Many species are extinct; fossil and extant forms in the same geographic region are related to each other (law of succession); the history of the Earth has been one of environmental change; and species have changed through time and there are transitional forms in the fossil record. The latter aspect of the fossil record is one that receives particular attention, in terms of both describing forms that are transitional between major taxa and in documenting evolution within lineages and clades.

One of the presumed problems with using the fossil record as evidence for evolution is that there are gaps between fossil forms and a smooth transition is not always documented. Darwin listed this as the first difficulty of the theory of descent with modification in *On the Origin of Species* (1859) and sought to answer the objection by pointing out the imperfect and intermittent nature of preservation of “parent-forms” and intermediate links. This explanation has been used subsequently on many occasions, and workers have sought to chronicle the resolution of the fossil and archeological records.

A particularly well-known fossil history is that of horses. Since the early work of Kovalevsky, many eminent paleontologists (including the rivals O. C. Marsh and Edward Drinker Cope) have studied horse evolution. The writings of George Gaylord Simpson have made the evolution of the horses one of the best-known, and debated, examples of long-term evolution. Simpson’s work has sometimes been characterized as advocating that the morphological trends in dental morphology, crown size, body size, skull size, preoptic dominance, brain size, and limb ratios were the result of phyletic evolution within a direct phylogenetic lineage, that is, a single line of gradual transformation from Eocene *Hyracotherium* to modern *Equus*. However, in *The Major Features of Evolution* (1953), Simpson points out that horse evolution is characterized by repeated and complex splitting (he specifically states that it is “bush-like”). He notes that there were no trends that continued throughout the history of the family in any line.

Figure 5a Trends in the evolution of horses. Simpson termed the early Miocene “the great transformation” of horse anatomy correlated with the spread of grassland. 5A presents the evolution of the skull, showing the increase in size and changes in cranial proportions including lengthening of the preorbital region; 5B depicts the trend toward increased brain size and complexity; 5C shows the trend toward increased crown height in upper molar teeth; 5D illustrates the molarization of premolars in the Eocene; 5E further depicts evolution of horse cheekteeth from brachydont, browsing teeth to hypsodont, grazing teeth for transverse shearing of abrasive grasses; 5F provides selected stages in the evolution of the forefoot, with a reduction of metapodials from 4 in *Hyracotherium* (eohippus) to 3 in *Mesohippus* and eventually to 1 in *Pliohippus* and *Equus*. Simpson viewed each column as a distinct mechanical type.

Contrary to creationist views, horse fossils chronicle large-scale evolutionary change even if the various genera were separated from one another by tens of millions of years. This is true regardless of whether horse evolution is interpreted in the context of anagenesis or as an example of “bushy,” cladogenetic evolution. Controversies regarding whether evolution has occurred within a lineage or clade by phyletic

evolution or punctuated equilibrium are debates regarding the tempo and pattern of morphological change, not whether change has occurred—both patterns document evolution. The same is true of contrasting interpretations of hominin evolution. However, creationist tracts sometimes cite sources emphasizing rectangular patterns of evolution to argue that evolution does not occur because of a purported lack of transitional forms; they demand evidence of phyletic evolution to support evolution as a fact.

Robert L. Carroll summarizes several well-documented cases of phyletic, directional evolution in late Cenozoic mammals in *Patterns and Processes of Vertebrate Evolution* (1997), including increase in length of limb bones and in the number of osteoderms in the giant armadillo (*Homesina*) lineage from Florida, morphology of the upper and lower molars in the sagebrush vole (*Laqurus curtatus*) over 287,000 years, and change in size and thickness of enamel in the molars of the water vole (*Arvicola cantiana*) over 300,000 years.

Examples of phyletic evolution have been chronicled for the primate fossil record, including within the Eocene *Cantius* lineage by W. C. Clyde and P. D. Gingerich and the Eocene *Tetoni*-*Pseudotetoni* lineage by Kenneth Rose and Thomas Bown. Meave Leakey discusses phyletic evolution in the *Theropithecus oswaldi* baboon lineage, from the upper Burgi Member Koobi Fora Formation to upper Bed II of Olduvai Gorge, in characters such as increase in com-

plexity of molars and their size compared with those of anterior teeth, decrease in size of canines and in the sectorial cusp of P₃, development of a “reversed cusp of Spee” on cheekteeth, increase in size of the glenoid process, and increase in estimated body weight. She interprets the evidence as representing an unbranched, evolving lineage that can be divided into the three subspecies: *T. oswaldi darti* (earliest in time and

Figure 5b

Source: From *Horses* by George Gaylord Simpson, copyright © 1951 by Oxford University Press, Inc. Used by permission of Oxford University Press, Inc.

smallest in size), *T. o. oswaldi* (intermediate) and *T. o. leakeyi* (latest and largest). Gerald G. Eck also interprets it as a phyletically evolving lineage but prefers to assign the earliest material, from Hadar and Makapansgat, to the species *T. darti* rather than using subspecific designation.

The recording of the tempo and pattern of change in individual characters is the methodology used in the studies cited above. It is preferable to plotting the range of species to document the pattern of evolution. The results produced by the latter often depend on the degree of variability in morphological parameters of each named species or genus, as well as on whether species are recognized on the basis of meristic characters or on those that vary continuously. Carroll states that the character-based approach often shows that evolution occurs in a mosaic manner: that different characters, or the same character at different stratigraphic levels, will show different tempos and patterns of evolution—an observation also discussed by Simpson in reference to horse evolution.

Variation and the Processes That Affect It

Genetic variation in characters is the raw material for evolution. As pointed out by Ronald Fisher in the fundamental theorem of natural selection and supported by subsequent experimentation by Francisco Ayala, evolution can occur only in populations that manifest genetic variation. Population geneticists have therefore spent considerable amounts of effort to measure variation. Since the pioneering work of Richard Lewontin and J. L. Hubby, gel electrophoresis has often been the technique employed, and estimates of genetic variation have been made by electrophoresis of proteins and both mitochondrial and nuclear DNA. Mean heterozygosity and the percentage of polymorphic loci are then calculated. Although John H. Gillespie argues that electrophoretic studies of enzymes may overestimate the amount of protein variation (because these proteins may be more polymorphic than are “typical” protein loci), the basic conclusion has been that natural populations are very

Figure 5c

Source: From *Horses* by George Gaylord Simpson, copyright © 1951 by Oxford University Press, Inc. Used by permission of Oxford University Press, Inc.

variable. Jeffrey B. Mitton, in *Selection in Natural Populations* (1997), states that 33% to 50% of enzyme loci are polymorphic and the average individual is polymorphic for 4% to 15% of its genes, but there is considerable variety in the percentage of genes that are polymorphic, from 0% in the modern cheetah and northern elephant seal to 100% in the mussel *Modiolus auriculatus*. Studies of plants and of *Peromyscus* mice suggest that the amount of genetic variation increases with the size of the geographic range.

High levels of variation counter the “classical model,” associated with Herman J. Muller, which held that populations in the wild would manifest little genetic variation: The model postulated that one allele of each gene would function best in each deme and would therefore be favored by natural selection. Almost all members of the population would be homozygous for this “wild-type” allele. If a superior

new mutation arises, it eventually becomes the new wild type. A population would evolve, but there would not be much genetic variation at any one time in the population. Mutations would be deleterious or have adaptive value, but would not be neutral in their effects.

With the discovery of large amounts of genetic variation in populations, two major competing models (balance and neutral mutation) sought to explain the maintenance of variation. The balance model, associated with Theodosius Dobzhansky, observes that many individuals are heterozygous at many loci: No single allele is best, and balancing selection would prevent a single allele from reaching very high frequency. Evolution would occur by gradual shifts in the frequency of alleles. Examples of heterozygote advantage, in which the heterozygote is fitter than is either homozygote (as in sickle-cell trait), bolster this argument. The neutral-mutation hypothesis (termed by Mark Ridley, the “purely neutral” theory) states that much, if not most, variation is selectively neutral because different genotypes are physiologically equivalent. Evolution is not driven so much by natural selection acting on alternate phenotypes/genotypes, but by genetic drift. The purely neutral

hypothesis predicts that larger populations will contain more genetic diversity than smaller ones, a prediction that appears to be contradicted by evidence.

Five processes influence the amount of variation in a population: mutation, recombination, gene flow, genetic drift, and natural selection. Mutation is any heritable change in the DNA, including both point mutations (for example, alleles that produce the varieties of hemoglobin) and chromosomal mutations (for example, polyploidy, polysomy). Recombination (crossing over), a process by which segments of homologous chromosomes are exchanged during Prophase I of meiosis, produces new combinations of alleles on chromosomes. Gene flow is the incorporation of alleles into the gene pool of a population from one or more other populations. The archetypal view is that it homogenizes genetic composition if it is the only operating factor; that is, the amount of gene flow between local populations influences the

degree to which each deme is an independent evolutionary unit, for if there is little gene flow, then each deme evolves independently from others. Gene flow would not only deter genetic drift but also potentially constrain the adaptive divergence of populations living in different environments. This issue is important because models of sympatric and parapatric speciation assume that if selection is strong enough, it can overwhelm the effects of gene flow and adaptive divergence and speciation can occur. Recent work by Andrew P. Hendry and Eric B. Taylor on lake and stream populations of the threespine stickleback fishes (*Gasterosteus aculeatus*) suggests that gene flow may constrain adaptive divergence, but to varying degrees, and that different traits do not respond in the same way to the same amount of gene flow.

Genetic drift (the “Sewall Wright effect”) is the random fluctuation of allele frequencies in effectively small populations: populations in which the number of individuals that actually breed is small. The basic premise is that small samples are often not representative of the range of genetic variation within a population and that the frequency of an allele in a small sample is unlikely to be equal to its frequency in the entire gene pool of a large population. Genetic drift is sometimes subdivided into continuous drift, intermittent drift, and the founder principle. The founder principle refers to situations in which populations are begun by a small number of colonists, which carry a fraction of the variability of the parental population, and allele frequencies differ from those of the parental population. When a population is subject to drift, the frequency of an allele will randomly change from one generation to the next until the allele is either fixed or lost (see Figure 7). It, therefore, reduces the amount of genetic variation within a population. Genetic drift has been produced in experimental populations of *Drosophila*, extensively treated mathematically, and modeled by computer simulation. It has been discussed in the microevolution of aboriginal Australians, the high incidence of hereditary eye disease and clinodactyly in the human island population of Tristan da Cunha, Ellis-van Creveld dwarfism in eastern Pennsylvanian Amish, and oculocutaneous albinism Type 2 in the Navajo.

Natural selection was defined by Darwin as the preservation of favorable individual differences and variations and the destruction of those that are disadvantageous. Selection acts directly on the phenotypes

Figure 5d

Source: From *Horses* by George Gaylord Simpson, copyright © 1951 by Oxford University Press, Inc. Used by permission of Oxford University Press, Inc.

of organisms and indirectly on their genotypes. In a genetic sense, alleles that promote greater ability to survive and reproduce in a particular environment (higher fitness) will leave more offspring than do less fit genotypes. The difference in frequency between various genotypes and phenotypes is a result of differences in ecology and not because of chance. Selection can occur at any stage of the life span, but it has maximal evolutionary impact when it acts on those age classes with the highest reproductive values. There are several basic premises: Phenotypic variation exists between individuals in a species; species have more offspring than can survive and reproduce; individuals with different phenotypes vary in their ability to survive and reproduce in a particular environment; and a portion of the ability to survive and reproduce is hereditary. While selection can cause evolution to occur in a population, a population may be at equilibrium as a result of natural selection and other processes.

Figure 5e

Source: From *Horses* by George Gaylord Simpson, copyright © 1951 by Oxford University Press, Inc. Used by permission of Oxford University Press, Inc.

It has been posited that selection can occur at any level of organization that fulfills the above premises: individual genes or larger parts of the genome (for example, meiotic drive in *Drosophila* and other taxa), individual organisms that have different genotypes and phenotypes, groups of organisms (discussion

generally focused on kin selection), and entire species (species selection, a tenant of punctuated equilibrium and a proposed mechanism to explain evolutionary trends without invoking phyletic evolution). Most of the naturalistic, experimental, and theoretical work centers on selection at the level of the individual. A number of well-known naturalistic cases are cited: melanism in peppered moths, survival of English sparrows during the winter of 1898, shell color polymorphism in British populations of European landsnails, water snakes on islands in western Lake Erie, heavy metal tolerance in the grass *Agrostis tenuis* on mine tailings, stolon length in populations of *Agrostis stolonifera* that grow in different environments, Batesian mimicry in Lepidoptera, and immunity to malaria in human populations with sickle-cell trait.

Neutral Theory and the Molecular Clock

While it is clear that the above five processes affect the amount of variation in populations, there is considerable debate over which mechanisms are most important in maintaining and changing the amount of genetic diversity. Natural selection and adaptation have received considerable attention, as has the purely neutral theory of molecular evolution (termed the “neoclassical theory” by Lewontin). In this hypothesis, most evolutionary changes in the DNA do not result from the action

of natural selection on variation. Rather, the mechanism of change is the random fixation of neutral or almost neutral mutants by the action of genetic drift. The probability of fixation of a neutral allele in a finite population is equal to the initial gene frequency (p); the rate of gene substitution is equal to the mutation

rate per locus. Most intraspecific protein and DNA polymorphisms are selectively neutral, and polymorphic alleles are maintained by a balance between origination by mutation or introduction into a population by gene flow and elimination by random extinction. Therefore, most molecular polymorphisms are not maintained by selection. It is predicted that genes that evolve rapidly will manifest high degrees of intraspecific variability.

Masatoshi Nei, in *Molecular Evolutionary Genetics* (1987), summarizes major points in the neutralist theory: many mutations at the nucleotide level are apparently neutral or nearly neutral; only a small proportion of mutations are advantageous; natural selection is a process that preserves advantageous mutations and eliminates disadvantageous ones; new mutations spread by genetic drift or by natural selection, but a large proportion of new mutations are eliminated by chance; and populations do not always have the genetic variation for new adaptation. In the neutralist paradigm, natural selection is invoked to explain the *loss* of disadvantageous mutations, but genetic drift to account for *fixation* of mutations. This differs from the selectionist approach, which invokes the effects of natural selection to explain both fixation and loss.

Related to the idea of selective neutrality is the molecular clock hypothesis, in which the rate of nucleotide or amino acid substitution is constant per site per year. The clock predicts a stochastically, not absolutely, constant rate of change. In his writings, Moto Kimura assumes that the rate of neutral mutation per year is almost constant among different organisms with very different generation spans, a conjecture that appears to depend on whether mutations are synonymous (silent) or nonsynonymous (replacement). The application of the molecular clock achieved notoriety by the work of Vincent Sarich, in which he concluded that the earliest possible date of divergence of the African apes and hominins was slightly more than 4 million years ago. This suggestion strongly contradicted the dominant

Figure 5f

Source: From *Horses* by George Gaylord Simpson, copyright © 1951 by Oxford University Press, Inc. Used by permission of Oxford University Press, Inc.

paradigm of the period, which placed the divergence in the Miocene with the identification of *Ramapithecus* as a hominin, and Sarich made the extreme statement that morphology was an unreliable indicator upon which to base estimates of dates of divergence. “Universal” rate calibrations have been suggested for mitochondrial DNA, albumin immunological distances, codon substitutions for cytochrome, myoglobin, alpha and beta hemoglobin, fibrinopeptides A and B and insulin, and the 16S rRNA gene.

The purely neutral and molecular clock hypotheses have received both support and criticism. In *The Genetic Basis of Evolutionary Change* (1974), Richard Lewontin extensively reviews the evidence for the maintenance of genetic variation available

Figure 6 Diagram of the evolution of characters in horses. Vertical lines are not proportional to the size of the changes, and the curves show rates, times, and directions of change in a relative way. Simpson's commentary states that trends were often different in rate and direction in different lines and in the same lines at different times, different trends occurred at different times and rates within a single functional system, a character may not show any trend for a long period even though it may have manifested a trend earlier or later in the fossil record, and a character may change from one "stable adaptive level" to another by a unique sequence of step-like shifts.

to that date, including the neutralist explanation and the suggestion that variation is maintained by frequency-dependent selection. More recent reviews include those by John C. Avise (*Molecular Markers, Natural History, and Evolution*, 1994), Gillespie (*The Causes of Molecular Evolution*, 1991), Roger Lewin (*Patterns in Evolution: The New Molecular View*, 1997), Nei (*Molecular Evolutionary Genetics*, 1987), and Ridley (*Evolution*, 2004), as well as many professional papers. Discussion can be divided into that which deals with the relative importance of selective neutrality in evolution and that which is aimed at

the assumptions and application of the molecular clock.

Because of the large amount of electrophoretic work that has been done on allozymes, examples of protein variation that can be shown to have important physiological effects and impact on fitness are used to counter the neutralist hypothesis. Different allozymes should work better in different environments: It should be possible to discover the kinetic and thermostability properties that make one variant work better than others in a particular environment and to find higher percentages in areas where it works better than other variants. There should also be increases and decreases in the relative percentages of allozymes as environments change. Studies that have sought to understand enzyme variation in an adaptive context include those of J. E. Graves and G. N. Somero on lactate dehydrogenase in four barracuda species, Ward Watt and colleagues on phosphoglucose isomerase in *Colias* butterflies, and D. A. Powers and P. M. Schulte on lactate dehydrogenase-B in the fish *Fundulus heteroclitus*.

Of particular interest are studies that have examined species on either side of the Isthmus of Panama, as the date of the origin of the isthmus is considered to be well established at about 3 to 3.1 million years ago. Results have been used to counter both the interpretation of allozyme variants as selectively neutral and the application of the molecular clock. Gillespie, citing the work of Graves and colleagues on pairs of fish species that are separated by the isthmus, argues that adaptive changes in the enzyme lactate dehydrogenase occur with only a 2-to-3-degree difference in average environmental temperature between the Atlantic and Pacific. Application of

Figure 7 Computer simulation of genetic drift over 19 generations in 24 hypothetical populations, each of 9 individuals. Note that the allele frequency changes at random from one generation to the next. If the simulation was continued, allele frequency would change erratically until the allele was either fixed ($p = 1$) or lost ($p = 0$) in each population.

Atlantic and Pacific comparisons to the molecular clock has yielded contradictory results, at least in the study of mtDNA. Avise and associates find that there is a definite separation in the mtDNA phylogeny of the Atlantic and Pacific populations of the green turtle (*Chelonia mydas*) but that the extent of the sequence divergence is 10 times lower than expected if the mammal-derived evolutionary rate of 2% divergence per million years is applied (Allan Wilson argues that this rate should be applicable to all animals). Avise concludes that mtDNA evolution is slower in turtles than in mammals. In contrast, a study by E. Bermingham and H. A. Lessios finds that the rate of divergence per million years for sea urchins is close to that calculated for mammals. Further complicating the molecular clock debate, Nancy Knowlton examined mtDNA and allozymes for snapping shrimp and concluded that the age of the biogeographic vicariance event probably does not accurately document the point at which gene flow stopped between the Atlantic and Pacific sides of the isthmus.

A revision of the original selective neutrality hypothesis is the “nearly neutral theory,” associated with T. Ohta, in which there are small positive or negative selection coefficients associated with mutations. In this paradigm, nearly neutral mutations are affected more by drift when populations are small,

but more by natural selection when populations are large. It may be argued that these effects of population size are true regardless of whether the mutation is nearly neutral or has a substantial positive or negative selection coefficient. Ridley extensively discusses this paradigm and perceives several advantages in comparison with the “purely neutral” hypothesis, including the prediction of a more erratic, less constant rate of evolution based on the influence of population size on whether slightly disadvantageous mutations will be affected by drift or selection.

Recent attention has also focused on microsatellite analysis rather than on the more traditional allozymes, mtDNA and RFLPs. Microsatellites are short, repeated sequences that are usually found in noncoding regions of nuclear DNA. They manifest a Mendelian pattern of inheritance, unlike mtDNA. Because of the large amount of variability in microsatellite arrays, researchers have used them in identification of parents/offspring and in forensic applications. It has also been suggested that they may show selective neutrality because their function is currently unknown. John Hawks and colleagues incorporate microsatellites in their discussion of population bottlenecks and Pleistocene hominin evolution: Variation in microsatellite base pairs should reflect population size expansions if the loci are selectively

neutral. However, as the authors point out, if it can be demonstrated that selection affects microsatellites, then variability in these regions need not indicate population expansions.

Evolution and Physical Anthropology

The Darwinian paradigm of evolution provides a conceptual framework in which the fossil record, primate behavior/ecology, and human and nonhuman primate population biology can be interpreted. While it was possible for Linnaeus to assign formal taxonomic names to primates (for example, *Cercopithecus aethiops*) and Baron Cuvier to describe *Adapis parisiensis* from the Montmartre gypsum quarries prior to Darwinism, the evolutionary paradigm provides a unifying, explanatory framework for physical anthropology. In their recent edition of *Principles of Human Evolution* (2004), Roger Lewin and Robert A. Foley discuss the four types of biological explanation; two varieties that are relevant to our discussion are explanations about adaptive value and evolutionary history. The former inquiries about the function of a trait or behavior and the latter about evolutionary history; both are central to the investigations conducted by physical anthropologists. It is not adequate to simply describe a morphological feature or behavior. Rather, it is crucial to (1) understand how that feature or behavior allows the individual to successfully interact with its environment and (2) to understand the diversity of extinct and extant primates in the context of common descent.

Physical anthropology has borrowed from other disciplines of evolutionary biology and ecology in these endeavors and, increasingly, contributed to the formulation of evolutionary concepts with application beyond the primates. Examples of concepts and techniques adapted from other areas of evolutionary biology and ecology are too numerous to completely enumerate here. The study of variation was a major contribution of the New Synthesis of evolutionary biology and was emphasized by papers in the seminal *Classification and Human Evolution* (1963), edited by Sherwood L. Washburn; it has formed a major aspect of primate taxonomy in both neontological and paleontological settings. Paradigms of phyletic evolution and punctuated equilibrium have been used in the interpretation of the primate fossil record. Various species concepts, such as the biological

species concept, the phylogenetic species concept, and the recognition species concept, have been applied to primates. Cladistic taxonomic philosophy and methodology, initially invented by the entomologist Willi Hennig, has been widely adopted and applied by physical anthropologists. The idea of the ring species (speciation by distance) was discussed by Yoel Rak to analyze hominin evolution in the Levant. It has been suggested that the phenomenon of nanism (dwarf forms), observed in island forms of ducks, hippopotami, elephants, and deer, may have occurred in hominin evolution, as documented by the recent discovery of *Homo floresiensis*. The ideas of sociobiology, employed outside of physical anthropology to explain social systems as diverse as eusocial insects and naked mole rats, are widely employed in modern primatology. And formulations associated with population genetics (such as the Hardy-Weinberg equilibrium and effective population size) are routinely used in the study of human and nonhuman primate population biology.

Physical anthropologists have been somewhat slower to apply their findings to larger evolutionary issues and concepts. This is unfortunate, because primate morphology, ecology, population biology, and behavior have been studied with an intensity that is unequalled in mammalogy. Long-term field studies, such as those of the Awash and Amboseli baboons, provide a wealth of detailed data that are of great benefit to the specialties of speciation research and behavioral ecology.

EVOLUTIONARY ANTHROPOLOGY

In a famous manifesto, the geneticist Theodosius Dobzhansky (1900–1975) claimed in 1973 that “nothing in biology makes sense except in the light of evolution.” One could also wonder if anything in anthropology makes sense except in the light of evolution. Indeed, there is a part of anthropology that does not deal with evolutionary issues. This is true for most of cultural anthropology, especially on the fringe of the sociology domain. It is even true for some aspects of physical anthropology. Medical anthropology deals with the health status of different populations in relation to different geographical and sociocultural environments. Forensic anthropology focuses mostly on identification of body remains, as well as of living subjects. It should be also underlined that anthropology was born and developed as a science in a preevolutionist period. Although the word *anthropologos* was used in antiquity, it is not before the Renaissance that it was used in a context involving goals of knowledge. Until the Classical Age, it was mostly centered on the “knowledge of one’s self.” However, dissertations on the moral nature of humans developed in parallel to studies of character and anatomical descriptions. From the middle of the 16th century, surgeons such as André Vesale (1514–1564) put emphasis on the anatomical determination of the human body. The word *anthropologia* appears for the first time in its anatomical meaning in a German book by Magnus Hundt (1449–1519),

published in 1501, *Anthropologium, de hominis dignitate, natura et proprietatibus*. In the 17th century, anthropology, the science of the study of humans, was divided between anatomy, addressing the body structure, and psychology, which speaks about the soul. In the 18th century, the first anthropological syntheses were developed, including the *Treaty of Man* by Georges-Louis de Buffon (1707–1788) and *The Anthropology or General Science of Man* published in 1788 by Alexandre Cesar Chavannes (1731–1800). Under the influence of the 18th-century naturalists such as Carl Linnaeus (1707–1778) and Buffon, anthropology became the natural history of humans. It was defined as such in 1795 by Johann Friedrich Blumenbach (1752–1840). The middle of the 19th century is marked by the creation of anthropological institutions, faculty chairs, and scientific societies in France, England, Germany, and the United States.

Revolutionary Perspectives on Anthropology

Anthropology was already established as an official science when three major events revolutionized perspectives on the place of humans in nature. In 1856, fossil remains of an extinct form of humans were discovered in the site of Feldhofer (Neandertal, Germany). Discoveries of fossil humans had already occurred in 1830 in Belgium (Engis) and in 1848 in Gibraltar (Forbe’s Quarry). However, although these specimens were later identified as genuine fossil hominids, the finding of Neandertal was the first recognized as such. It is not before the latter part of the 19th century that the concept of Neandertals as a distinct and extinct form of humans was universally accepted. Second, in 1859, Charles Darwin (1809–1882) published his master work, *On the Origin of Species by Means of Natural Selection*. The notion of evolutionary change in living species predated Darwin, and the French scientist Jean-Baptiste Lamarck (1744–1829) can be considered the father of the evolution concept in its biological meaning. However, Lamarck failed to propose a valid mechanism to explain the mechanism of evolutionary processes. The primary contribution of Darwin was the identification of natural selection as a major force driving evolutionary changes. The third event of major importance also occurred in 1859. English archaeologists and geologists including Hugh Falconer (1808–1865), Joseph Prestwich (1812–1896), and Sir John Evans (1823–1908) accepted the association of

human-made Paleolithic flint implements with extinct fauna in geological ancient deposits that had been described by Jacques Boucher de Perthes (1788–1868) in northern France. Although a large portion of anthropological studies still remained out of the evolutionary perspective, beginning with this period, prehistoric archaeology and human paleontology became important topics of research for cultural and physical anthropologists. Because of the complexity of the roots of anthropology, this science is the crossing point of several distinct fields of knowledge and is multidisciplinary in nature. Evolutionary anthropology can be defined more as a perspective than as a science. It is the synthesis of the various fields of anthropological studies addressing the behavioral and biological nature of humans and their mechanisms of emergence through time.

Human Evolutionary Processes

Looking at the anatomical changes of humans in a remote past, and at the changes in technical skills, is the most obvious way to approach human evolutionary processes. Indeed, paleoanthropology represents the core of evolutionary anthropology and is essentially the field that unites all the others. The term *paleoanthropology* is sometimes understood as a synonym of *human paleontology*; however, more often it encompasses paleontological and archaeological studies. In the course of their evolution, humans have combined biological and cultural adaptations while they geographically expanded. Even if technical responses to the challenges offered by the conquest of new geographic and ecological niches became preponderant, it is most important to consider the two aspects of human adaptation and their complex interactions. One defining aspect of human paleontology lies in the fact that the study of rare and precious specimens remains the core of the discipline. The fossil hominids give a very fragmentary and discontinuous picture of the past evolution of humans. Traditionally, they have been described and compared in order to provide a picture of the phylogenetic tree of our ancestors and direct relatives. One major problem in this process is related to the difficulty in accessing specimens. After discovery, they can remain unpublished for long periods, and later, they can be possibly under the care of curators more preoccupied by conservation than by scientific studies. Since the

1990s, new techniques, primarily from medical imaging (for example, CT scanning) have allowed development of new approaches for the study of these fossils. “Virtual paleoanthropology” is based on the utilization of 3-D images that allow virtual extraction and reconstruction, precise quantitative analyses of internal structures, and also mathematical analyses of the shape through 3-D morphometrics and the modelling of ontogenetic processes, biomechanical properties, and evolutionary changes themselves. Although the resolution of these 3-D images is still far from perfect, one can expect that in the future their use will reduce the need to access the specimens. Work on the original specimens will be restricted to specific issues such as the analysis of fine anatomical details, cut marks, microstructure, and chemical composition.

A new series of approaches have developed, inherited primarily from histology, geochemistry, and biochemistry. With the rise of non- (or less) destructive methods, this field is rapidly expanding. In parallel, it should be noted, there have been growing interests in biological issues, for example, diet or growth processes, that are not directly related to phylogenetic issues. Microstructural studies have developed mostly in the field of dental anthropology. Several types of incremental mineralized structures, to date, represent the primary way to assess life history in extinct species. This emergence of microstructural analyses has been made possible by large technological advances in microscopy.

Chemical analyses of fossil specimens aimed to reconstruct paleobiological features are mostly concerned with extraction of organic molecules. The sequencing of small fragments of mitochondrial DNA extracted from fossil remains of humans and animals has opened a new area of paleobiological study. The analysis of stable isotopes, mostly carbon, oxygen, and nitrogen, represents another major field of research in paleoanthropology. Stable isotope rate is an essential source of information about the environment and the diet of individuals during their lifetimes. In the future, issues such as migration and seasonality will become accessible through these kinds of studies. These methods may also provide a better knowledge of the environmental conditions of humans in the continental environment.

Paleoanthropologists place a great deal of emphasis on the understanding of evolutionary processes. Important methodological progress was made in the 1970s with the rise of cladistic methods. However,

specialists still investigate the significance of the features used in phylogenetic analysis. To what extent are they genetically determined, or depend on environmental conditions and behaviors? Are they homologous from one species to another? These are the questions that need resolution in order to gain better insight into phylogenetic relationships. Among the paleobiological issues, changes in growth and development processes along life history are increasingly seen as a powerful mechanism to explain evolutionary changes. A consistent effort is applied to the establishment of developmental trajectories in extant hominoids and extinct hominins. Other aspects of the biology of extinct species are also accessible through the progress of archaeological sciences. Proteins and lipids are extracted with increasing frequency from fossil bones and may give us access to physiological features that have been inaccessible to date. Paleodemographic questions related not only to life history and longevity but also to population size and their fluctuations through environmental changes are also of high interest.

Importance of Fieldwork

A very important aspect of paleoanthropological studies is related to fieldwork. The spectacular increase of fossil material in the last two or three decades, resulting in a much better understanding of human evolutionary history, is mainly the consequence of the development of field surveys and excavations. This is also where, often, human paleontologists and prehistoric archaeologists meet. Contrasting with the rarity of ancient human remains, artifacts are found in large numbers in areas where humans have lived in the past. The occurrence of stone artifacts is the most reliable parameter to assess the occupation of given geographical areas through geological time. However, the abundance of stone artifacts provides a biased picture of ancient behaviors and technologies.

The evidence for the “Stone Age” comes mostly from the fact that tools manufactured by flaking of hard stones are virtually indestructible and can accumulate in very large numbers over long periods of time. Most of the Pleistocene was actually, rather, a “Wood Age,” at least in some parts of the world. The study of archaeological sites with mixed artifacts, faunal remains, and sometimes structures such as fireplaces left by humans aim to separate human activities from natural processes. Most of the time, it is a somewhat naïve view to assume that these accumulations represent “habitats.” In many cases, human occupation was discontinuous and other mammals such as carnivores may have played a major role in the accumulation and alteration of the faunal remains. The artifacts themselves could be displaced in a secondary accumulation. Finally, the whole site may have undergone significant geological modifications. Site formation and taphonomical studies are important issues in the interpretation of archaeological sites. The density and distribution of the human occupations in the landscape are related to environmental factors that one tries to discriminate. These data help us to understand the history of the peopling, past demographic fluctuations and the way ancient humans could exploit the environment. Zooarchaeology research aims to analyze the faunal remains in order to reconstruct hunting (or scavenging) strategies, carcass processing, and transportation and, in a broader context,

Photo courtesy of Max-Planck-Institute, Leipzig, Germany

how ancient hunter-gatherers interacted with the animal world. The stone and bone artifacts themselves are the objects of many studies. They were, in the past, considered as chronological markers, but today the technology leading to their production has become of greater interest and gives us some clues about the skills and cognitive abilities of ancient humans. The raw materials that have been used by ancient humans also inform us about the patterns of land occupation and possible long-distance exchanges between human groups. For the most recent periods of prehistory, the occurrence of symbolic manifestations such as body ornaments, geometric signs, paintings, engravings, and sculptures reveals the development of modern thinking. It can give some clues on the major changes in the social organization in humans and, likely also, in the development of modern language. For these late periods, it is possible to use the archaeological evidence to identify ancient ethnocultural entities.

Study of Nonhuman Primates

Because evolutionary anthropology is mainly concerned with the question, “What makes humans different?” the study of nonhuman primates represents an important part of its scope. In this perspective, primate studies focus on biological and behavioral aspects. A large proportion of evolutionary studies have been dedicated to comparative anatomy and

physiology. Attention has also been paid to differences in the process of growth and development among different species of monkeys and apes. Primate paleontology is an important field of research, as it brings light on the phylogenetic relationships of living and extinct species and also on the adaptive strategies of the different groups. However, with respect to phylogeny, molecular studies and genetics have as well made a very significant contribution in the last decade. Finally, social organization and behavior of living apes and

monkeys is also an important field of research that aids in understanding the emergence of hominin societies.

Among the primates, the species that are the closest to our own are classified together with humans and their ancestors into the superfamily of hominoids. This is the reason that many studies put emphasis on the gibbons, the orangutans, and our even closer relatives, the African apes: gorillas, common chimpanzees, and bonobos. One major problem faced by evolutionary anthropology lies in the fact that, in the wild, these species are greatly endangered. Although they may survive only in zoos in the near future, there is still a lot to learn from them. This is especially true in the areas of development, genetics, and ethology (the science of animal behavior). Unfortunately, life in captivity will make many questions regarding these issues inaccessible. In the past, hominoids have been a much more successful group than they are today. The human species, which covers an entire planet, represents an exception. In fact, the number of species of hominoids has been reduced since the Miocene period. Other groups of primates (cercopithecoids), on the contrary, have undergone an expansion during the same period. Hominoids represent a group of middle- to large-bodied primates, primarily adapted to forested or semiforested environments. Analyzing the anatomy of the living and fossil species is of crucial interest to understand human

origins. Indeed, hominins achieved a very unique adaptive model. They adapted to a new ecological niche for hominoids, in particular the open environments of the middle and high latitudes. They adapted to an entirely new locomotor repertoire with the development of bipedalism. They accessed new diets with the developments of carnivory and hunting. Finally, they developed cultural and technical adaptations to a level unequalled in the primate world. In an evolutionary perspective, primatology is interested in analyzing these differences between humans and apes but also in the separate emergence of some features once considered unique to humans in the other hominoids. In terms of behavior, it is important to understand how the variety of social systems developed by apes responds to different adaptive strategies. This includes social organization and reproductive patterns that can be quite different from one species to another. The types of cognitive abilities that have been developed by these different species are under the scrutiny of primatologists. Sociocognitive processes, including communication, cooperation, social interactions, and learning, are also very important to analyze.

It is fascinating to consider the behavioral diversity that can exist between different populations of the same species of apes. One of the most important discoveries of the last decades has been the revelation of “ape cultures.” Different groups within the same species can develop “traditions.” This issue has been studied especially in common chimpanzees in which technical skills involving the use of tools such as hammers and anvils, but also “fishing sticks” to acquire insects, have been described. These technologies, as well as specific behaviors such as hunting strategies for a spectrum of prey, are transmitted between generations and vary from one group to another. Wherever possible, wild apes are studied by direct observation in the field, which implies long-term projects dedicated to the follow groups and individuals over long periods of time. In the course of these field projects, some biological aspects are also analyzed, and molecular geneticists analyze samples of feces and hair collected noninvasively to address questions concerning paternity, reproductive strategies, relatedness between and within social units and phylogeny.

Evolutionary anthropological genetics investigates the genetic history of primates in general and humans in particular. This field of evolutionary anthropology focuses on the processes directly affecting the evolution

of the genome, such as mutation, recombination, natural selection, and genetic drift. Rebuilding the detailed history of different lineages in terms of demographic evolution and phylogenetic relationships is also of great interest in this discipline. With increasing frequency, studies are dedicated to living great apes, which provide a very important comparative model for the evolution of early hominids even if, in general, their demographic and genetic evolution differed in important ways from our own over the course of the last 2 million years. Molecular phylogeny has provided invaluable information on the origin, relationships, and times of divergence for the different species of hominoids, including humans. Another important aspect of genetic studies is dedicated to examining the ways in which the genome determines development and function of organisms. The comparison of the gene expression patterns in various tissues in primates has given us a greater understanding of many biological aspects of the human nature. The history of ancient populations, or even extinct species, can be approached by using genetic analyses. It is possible to extract, amplify, and sequence mitochondrial DNA fragments from fossils, such as Neandertals 40,000 years old. This genetic information helps us to establish the phylogenetic status and times of divergence of such an extinct species. It provides insights into the variation of the size of these ancient populations throughout their evolution. Fossil DNA is as well extracted from non-human mammals, which were the hunted game or the competitors of our ancestors and relatives. Such genetic material is extracted from bone remains but also from coprolites (fossil feces). It provides data for interesting comparisons, as animal material is much more abundant than are human fossils. A major challenge faced by paleogenetics results from the problem of contamination of ancient samples by modern human DNA, which is abundant in our present environment. Paradoxically, it is easier to identify genuine fossil DNA in extinct humans such as Neandertals than in more recent modern populations.

Population Genetics

Since the 1980s, population genetics has emerged as a major methodological framework in which to understand the origin, migration, and evolutionary history of the modern humans and their direct ancestors.

The analysis of genetic variation in living populations has been intensively explored in evolutionary anthropological research. This is particularly true for research examining variation in the mitochondrial DNA, transmitted from mother to offspring, and in the Y chromosome, exclusively transmitted from fathers to sons. Most of these studies establish a recent origin of modern humans (between 200,000 and 100,000 BP), most likely in Africa. They suggest past bottlenecks of ancient populations and indicate a late dispersal of modern populations throughout Eurasia and Australia, and even more recently, throughout the Americas and the Pacific Islands. Genetic analysis provides not only a general tree for human populations but also some indications of the timing of colonization by modern humans. In the details, it can bring some light on interactions between groups, mating strategies, differences in mobility between genders, or the geographical origin of pioneer groups like those that colonized the Pacific. Population genetics often interacts with linguistics in order to elucidate the detailed history of human groups. Like genes, languages are transmitted from parents to their children. Words and grammatical structures also undergo “mutations,” which result in a diversification and divergence of numerous linguistic groups.

Language is indeed a unique feature of humans, and a great deal of effort is dedicated to the study of its structure and evolution. Although “communication” is common among other animal species, human language distinguishes itself by the complexity of sounds that the human vocal tract is capable of producing, as well as the control of sound production at a rapid time scale. It is also characterized by the complexity of its syntax, which facilitates the organization of concepts in a way that goes much further than the simple combination of vocal signals. The question of the origin of language is difficult and much debated. Anatomical features allowing the physical production of human languages, as well as the cerebral abilities necessary for its manifestation, may well have been selected independently and for other needs in the course of hominin evolution. Linguists are very much interested in establishing the common features of all human languages (“language universals”). Some have even tried to delineate some traits of an original language ancestral to all the others. Language universals may result primarily from the way the human mind is able to conceptualize

ideas and articulate them into speech. Other aspects of linguistic studies are dedicated to the way languages can differ from each other and how they vary over the course of time. Understanding these processes allows the construction of language trees at different scales. Families of languages descending from a single ancestor have been established. Sometimes they present distribution that can be related to the spread, development, or movement of large human groups. Establishing the relationships between these families into larger units has proven to be a more difficult task. The fact that linguistic traits can be imposed or adopted from one group to another through complex historical processes greatly complicates comparisons of archaeological, genetic, and linguistic features in order to rebuild the history of different populations.

Developmental and Comparative Psychology

Developmental and comparative psychology is also crucial to the understanding of what makes humans different. This field of research investigates cognitive and social features of humans and compares them to those of other primates. These studies aim to establish the abilities that have been uniquely developed by humans. Studies on large apes are generally conducted through experiments exploring the abilities of the different species. The field also explores individual variation within groups. Several types of cognition are explored and are generally grouped into two areas referred to as social cognition and physical cognition. The first is relevant to how individuals are able to understand the actions and intentions of other individuals. Analyzing the learning and imitation processes is a main issue in the analysis of social cognition. Physical cognition is implemented by individuals in their interactions with their environment. Experimental psychology is also much interested in the development of human children. Humans contrast with other primates with an extended period of brain maturation occurring after birth while the individual is already interacting with his or her physical and social environment. The learning period is longer in humans than in any other species of primates. The acquisition of language is one of the most spectacular changes during this period. Psychologists are interested in how humans read and understand the minds of other people and develop social skills during the

first year of life. Techniques of medical imaging have opened the possibility to connect the brain development with the acquisition of specific abilities. In older children, the development of social and physical cognition is also explored. The acquisition of language is, of course, a main focus of interest. Its learning processes are investigated in a clinical way, as well as cross-culturally.

Evolutionary psychology also analyzes human behavior in adults. The reproductive strategies, mating patterns, and parental investment in children have played a particularly important role in the past and present evolution of human groups. However, the field extends to many other behaviors, such as reciprocity and cooperation between individuals, or even violence and homicide. The determinism of these behaviors and/or of their transmission is often difficult to clarify, as they are also depending on cultural and economical conditions. Ultimately, cultural features in past and present societies can also be assessed in an evolutionary perspective.

The animal nature of humans has always been a matter of fascination, if not of anxiety, for us. For centuries, philosophers, writers, and scientists have tried to define the unique nature of humans and to separate them from the animal world. Evolutionary anthropology deals with the oldest origins of humans, among the primates, and utilizes our closest relatives as comparative models. It interprets the complex features of human behavior in the light of adaptation and faces the challenge of unweaving the complex interactions between biology and culture at work in the course of human evolution.

EVOLUTIONARY EPISTEMOLOGY

Evolutionary epistemology considers the scientific processes and bounds of *knowledge*, with an emphasis on natural selection as the crucial source of sensate cognition by which organisms adapt to their environments. This mode of naturalistic epistemology contrasts significantly with the traditional *transcendent*

formulation, which presupposes no particular format of knowledge. The traditional approach traces to Plato, who sought to differentiate knowledge from true belief insofar as the true belief does not require *justification*. Later rational empiricists, notably Descartes, sought to identify and further systematize the bounds and processes of human knowledge, particularly as it is organized in neuromental assemblages. Ultimately, the two approaches converge in the aim of traditional epistemology to reconstruct human knowledge via justification that separates knowledge from merely true beliefs.

However, Darwinian insights of the 19th century cast humans as natural beings arising in the course of evolution. As means of human knowledge and belief are likewise expressions of natural selection, they are perhaps best analyzed and systematized by the scientific method in general and the principles of evolution more specifically. Hence, there is a pragmatic, not transcendent, basis for epistemics rooted in a priori facts of evolutionary biology and psychology.

Evolutionary epistemology has two main component interests: adaptation as it occurs both through phylogeny or within individual development and understanding the legacy of ideas, concepts, and cultural tropes in which knowledge exists. With respect to adaptation, the phylogenetic analysis of evolutionary epistemology takes up how the mechanisms of sentience *fit* the world. This is a direct extension of Darwinian concepts to philosophy insofar as the heuristic function of knowledge is to enhance reproductive fitness. Thus, evolutionary epistemology of adaptation posits, in the first instance, that the processes and bounds of knowledge accumulate and evolve as the result of variation and selection. Otherwise, the ontogenic aspect of adaptation takes up how individual ontogeny of knowledge is also an expression of processes in which variation and selection play a central role. Trial-and-error learning or the development of scientific theories are obvious examples of this second element in the evolutionary epistemology of adaptation.

These direct correspondences between mechanisms of evolution with those of ideation were noted by Darwin, Spencer, Romanes, Poincaré, Dewey, William James, and others. However, it was only more recently that evolutionary epistemology was systematized as a cogent philosophical approach to knowledge, first by Karl Popper and then by Donald T. Campbell and others.

Popper emphasized *conjecture* and *refutation* as key elements of valid science and also noted that every scientific theory must be *falsifiable*; that is, it must be subject to deselection. Such an iterative trial-and-error process accumulates knowledge about the world. In his later work, Popper emphasized analogies between this iterative conjecture/refutation process and the very similar operations of natural selection, in what he deemed evolutionary epistemology.

Campbell greatly elaborates this approach to take in the whole of evolutionary neuromental processes subserving knowledge in sentient beings. Campbell's project directly applies Darwinian principles to educe three main provisos:

1. *Blind variation and selective retention*: Primitive processes for new knowledge are *blind*. However, even without foresight as to what may be learned, ineffective elements are deselected whereas adaptive elements are retained.
2. *Vicarious selector*: Trial-and-error processes recede as "fit" knowledge accumulates and functions as a selector predictive of environmental selective pressures.
3. *Nested hierarchy*: Retained selectors may also be subject to variation and selection at a higher level. This fosters cognitive-emotive-rational assemblages at higher levels of ever-more-intelligent adaptive systems.

But there is another strand of evolutionary epistemology beyond this cognitive neurobiological perspective, as there is a need to explain the evolution of epistemic norms of ideation itself. To this end, models of scientific theory and human culture are constructed in a manner compatible with evolutionary neurobiology. Ultimately, this other main component relates to semiotics and meaning making as it analyzes the scientific method itself in evolutionary terms as varying hypotheses are selected on the accumulation of useful information.

These two interrelated but quite different aspects of the field have become known, respectively, as the *evolution of epistemological mechanisms* (EEM) and *evolutionary epistemology of theories* (EET). Valid EEM selectionist explanations (for example, how the brain works) do not in themselves explicate how systems of human knowledge are assembled.

Conversely, valid EET explanations of how human knowledge systems are selected do not in themselves explicate the neurobiological mechanisms of perception or cognition.

Indeed, one major criticism of evolutionary epistemology is that it traverses and perhaps conflates several levels and domains of evolution—biological, sensory, perceptual, cognitive, emotional, social, and linguistic—even as it also addresses the rather different realm of the evolution of scientific concepts. A more complete epistemology of human knowledge must explain how these processes interact within both phylogeny and individual development as well as with respect to the evolution of scientific culture. Thus, some argue that neither EEM nor EET analyses are proper works of epistemology, at least as epistemology is traditionally a normative discipline. However, the rigorous consideration of evolutionary possibilities and constraints with respect to processes and bounds of knowledge has greatly enriched traditional epistemology. It has also brought attention to important issues of practical importance in an era marked by major progress in neuromental sciences.

Evolutionary epistemology may best offer descriptive accounts of knowledge mechanisms, whereas traditional epistemology attends to the resolution of prescriptive issues of continuing philosophical interest. At the very least, evolutionary epistemology enhances traditional methods as it helps identify implausible normative prescriptive notions that are inconsistent with evolutionary perspectives concerning human understanding.

EVOLUTIONARY ETHICS

The obvious as well as the ideal place from which to begin a consideration both of social Darwinism and of evolutionary ethics is the work of Charles Darwin and the ideas he developed and presented in *On the Origin of Species* (1859), which advocates both of social Darwinism and of evolutionary ethics have tried to apply more widely. This is not, of course, to say that Darwin had no intellectual ancestors, any more than it is to say that biological theory has stood still since his death. To say or to suggest either of these things would be wrong.

It would not even be true to say that nothing was published with any claim to the label “evolutionary ethics” until after the first appearance of *On the Origin of Species*. Herbert Spencer was strictly correct when, in the general preface to *The Principles of Ethics*, he claimed that the “doctrine of organic evolution” as it applied to humans had come earlier than that. Spencer was on this occasion referring to his *Social Statics*, first issued at the end of 1850 and containing an outline of the ethical ideas he was about to develop. He could also have claimed, and elsewhere did claim, to have been the first to use the notion of the “survival of the fittest” in an evolutionary context, in an article in the *Westminster Review* for 1852.

The very phrase a “struggle for existence,” which epitomizes the gladiatorial view of human life so often taken to be the true moral to be drawn from *On the Origin of Species*, is to be found already, in a similar context, in 1798, in what should be called “the first essay of Malthus on *The Principle of Population*,” in order to distinguish it from the substantially different work Malthus issued in 1803 as if it were merely a second edition. Darwin himself acknowledges his debt to this first essay of Malthus in *On the Origin of Species*. Nevertheless, after all due cautions have been given, it is *On the Origin of Species* that is, and must be, the reference point here. It was the ideas of that work which the forerunners foreran. It was the triumph in biology of the theory that it presented which lends vicarious prestige to whatever can be put forward as Darwinism.

Since many sharp things need to be said about some particular sorts of attempts to develop an evolutionary ethic, it becomes important to emphasize from the beginning that the desires to connect, to see microcosms in relation to the macrocosm, are in

themselves excellent; and certainly, they should be shared and not despised by anyone who aspires to the title of “philosopher.” It is therefore neither surprising nor discreditable that in every generation since Darwin, some of the liveliest and least blinkered of students of biology have wanted to explore the possibility of connections between Darwinian evolution and ethics.

The main reason why professional philosophers are apt very brusquely to dismiss all such efforts is that we mistake it that they must involve the committing of what philosophers call the “naturalistic fallacy.” The nerve of this fallacy is the attempt to deduce a conclusion about what either *ought* to be or *ought to have been* the case from premises stating only, in morally neutral terms, what either *actually is* or *actually was* the case. Once this fallacy has been recognized for what it is, it may seem that with evolutionary ethics, this is both the heart of the matter and the end of the affair.

This is not good enough. Certainly, the first necessity when a logical fallacy has been committed is to show what was going wrong in that particular case and then perhaps to reinforce the lesson by citing a few further cases of committing the same fallacy in various other areas of discourse. But to stop there would be to fail to appreciate that the source of the very idea of an evolutionary ethic, which Darwin himself did not accept, lies in *On the Origin of Species*. The danger of Darwin’s pointedly paradoxical expression “natural selection,” and this danger has often been realized, is that it can mislead people to overlook that this sort of selection is blind and nonrational, which is precisely the point. Once this point is missed, it is easy, especially if you are already apt to see nature as a mentor, to go on to take natural selection as a sort of supreme court of normative appeal—and this despite, or in many cases doubtless because of, the time-serving character of the criterion of fitness by which this sort of selection operates. Such ideas may then be, and often have been, regarded as the biological application of the Hegelian slogan, “World history is the world’s court of judgment.”

These apotheoses of natural selection take many forms. Perhaps the most interesting and important of such misconceptions, and one from which Darwin himself was not altogether free, is that the deductive argument that was the core of his theory proves some sort of law of progressive development. Thus, Darwin concludes his chapter on instincts with the sentence:

“Finally, it may not be a logical deduction, but to my imagination it is far more satisfactory to look at such instincts as the young cuckoo ejecting its foster brothers, ants making slaves . . . not as specially endowed or created instincts, but as small consequences of one general law leading to the advancement of all organic beings—namely multiply, vary, let the strongest live and the weakest die.”

Again in the penultimate paragraph of the whole book, Darwin writes: “As all the living forms of life are the lineal descendents of those which lived long before the Cambrian epoch we may feel certain that . . . no cataclysm has desolated the whole world. Hence we may look with some confidence to a secure future of great length. And as natural selection works solely by and for the good of each being, all corporeal and mental endowments will tend to progress towards perfection.”

The first of these two passages is not, perhaps, as clear and explicit as one could wish. But in the light of the unhesitating concluding sentence of the second, we may perhaps take it that “what may not be a logical deduction” is not the “one general law leading to the advancement of all organic beings,” but rather its implications as regards the more unattractive instincts. Certainly Darwin here was offering natural selection as a guarantee of progress and as both a descriptive and a prescriptive law. Equally certain is that this guarantee was not in fact warranted by his theory. Indeed, neither of the conclusions of this second passage can be justified as deductions from the theory alone.

The first was, on the evidence available to Darwin, an entirely reasonable inductive extrapolation. It is only since the beginning of the atomic era that we humans have acquired any grounds for anxiety about the survival prospects of our own species. The second conclusion never was justified. To choose is necessarily to exclude, and there would seem to be no reason at all, and certainly none within the theory, for saying of every individual who loses out in the struggle for existence that that must be for its own good. Applied not to individuals but to species, the statement might seem to find some justification in the now notorious fact that most actual variations are unfavorable. But because survival is, in theory, the criterion of fitness, and hence of what counts as favorable, the only good that is guaranteed is the survival of whatever makes for survival; and this good is not necessarily good by any independent standard.

Although we would be mistaken if we believed that Darwin's theory implies a general law of progressive development, the idea that it does has been perennially tempting. Since it surely is the case that in every epoch of the fossil record, fresh possibilities of life have been realized, and since it also seems that the most complex of these in each epoch have been more elaborate than the most sophisticated achievements of the previous period, and since we ourselves are among the latest products of such development, it is easy to pick out a trend that we can scarcely regard as anything but progressive.

To pick out a progressive trend is, of course, made still easier if we allow ourselves to misconstrue in a normative sense the paleontologists' purely spatio-temporal use of the terms "higher" and "lower" to characterize first the strata and then the creatures that first appear in those strata. It was not for nothing that Darwin pinned into his copy of *Vestiges of the Natural History of Creation* the memorandum slip, "Never use the words *higher* and *lower*."

Once a trend has been thus identified it may seem a short step from a trend to *the* trend, another equally short step from *the* trend to a *law of tendency*, and so again finally, from a law of tendency to a universal overriding *law of development*. This slippery slope is greased by the fact, first, that the crucial mechanism is called natural selection or the survival of the fittest and, second, that the core of Darwin's theory is a deductive argument that certainly does prove that natural selection is operating and is therefore ensuring the survival of the fittest.

But a trend is a very different thing from a law of tendency. There is a trend if there has been a direction in the development so far, whether or not there is any reason to think that things will continue to develop along this line. But to assert a law of tendency is to say that something always has occurred and always will occur, except in so far as this tendency was or will be inhibited by some overriding force. Furthermore, a law of tendency is a very different thing from an absolute law of development. The former may obtain even though the tendency in question is never in fact fully realized; the first law of motion and Malthus's principle of population are not disproved by the observations that in fact there always are impressed forces and countervailing checks. But an absolute law of development would state that some particular line of evolution is absolutely inevitable, that it neither will or would be prevented by any counteracting causes.

Darwin himself seems never to have gone further than to suggest (as in the two passages already quoted) that his theory might warrant a conclusion of the first and weaker kind: that there is in the evolution of all living things an inherent tendency to progress. It was left to others reviewing evolutionary biology in the light of their own various preconceptions about the (supposedly) predestined lines of nonhuman development to discern in Darwinism the deeper foundation for, or the wider background of, their own supposedly discovering absolute laws of human progress.

By far the most interesting and most important case is that of the two most famous young Hegelians, Karl Marx and Friedrich Engels. In his preface to the first German edition of *Das Kapital*, Marx wrote, "When a society has got upon the right track for the discovery of the natural laws of its movement—and it is the ultimate aim of this work to lay bare the economic law of motion of modern society—it can neither clear by bold leaps, nor remove by legal enactments, the obstacles offered by the successive phases of its normal development. But it can shorten and lessen the birth pangs." And in his speech at Marx's graveside, Engels claimed, "Just as Darwin discovered the law of development of organic nature, so Marx discovered the law of development of human history."

The crucial distinctions between actual trends, laws of tendency, and absolute laws of development can be instructively applied to the writings of two 20th-century British social Darwinists: Julian Huxley, who, after first acquiring his Fellowship of the Royal Society as a result of his biological research, eventually went on to become the first director of UNESCO (United Nations Educational, Scientific, and Cultural Organization), and Joseph Needham, who, after first acquiring his Fellowship of the Royal Society in the same way, went on, with considerable assistance from Chinese colleagues, to produce his massive study, *Science and Civilization in Ancient China*.

Huxley in a famous essay on "Progress, Biological and Other" quoted one of the sentences from Darwin we have just quoted: "As natural selection works solely by and for the good of each being, all corporeal and mental endowments will tend to progress towards perfection." It is, I think, clear that Huxley, if pressed, would never claim to be revealing more than a law of tendency, and usually only an actual trend.

Huxley starts by urging that the most fundamental need of man as man is "to discover something, some

being or power, some force or tendency . . . moulding the destinies of the world—something not himself, greater than himself, with which [he can] harmonize his nature . . . repose his doubts . . . achieve confidence and hope.” He then offers “to show how the facts of evolutionary biology provide us, in the shape of a verifiable doctrine of progress, with one of the elements most essential to any such externally-grounded conception of God.” He later concludes that “the fact of progress emerging from pain and imperfection . . . is an intellectual prop which can support the distressed and questioning mind, and be incorporated into the common theology of the future.”

Although Julian Huxley is certainly not adequately insistent upon the first crucial distinction between an actual trend and a force, he does in the following essay on “Biology and Sociology” fairly clearly repudiate the suggestion that the actual progressive direction of development to be discerned in evolutionary biology and elsewhere necessarily reveals an absolute law of progressive development: “When we look into the trend of biological evolution, we find as a matter of fact that it has operated to produce on the whole what we find good . . . This is not to say that progress is an inevitable “law of nature,” but that it has actually occurred. . . .” This strongest idea of a law of inevitable development, rejected by Huxley, is in fact urged, eloquently and unequivocally, by Joseph Needham in two books of essays, *Time: The Refreshing River* and *History Is on Our Side*. Much of their interest for us lies in the attempted synthesis of biological science, Marxist historical pseudoscience, and ritualistic Christian religion. For the author was at the time of writing a leading biochemist, an active member of the Communist Party, and a practicing Christian.

Thus, Needham was able to write that the historical process was the organizer of the City of God. “The new world-order of social justice and comradeship, the rational and classless world state, is not a wild idealistic dream, but a logical extrapolation from the whole course of evolution, having no less authority than that behind it, and therefore of all faiths the most rational.”

—Antony Flew

EVOLUTIONARY ETHICS

An *Encyclopedia of Philosophy* writes of evolutionary ethics: “Morality is universal, whereas biologically useful altruism is particular favoring the family or the group over others. Evolutionary ethics is, on a philosopher’s time-scale, a very new approach to ethics. Though interdisciplinary approaches between scientists and philosophers have the potential to generate important new ideas, evolutionary ethics still has a long way to go.”

One area in which evolutionary ethics has been set on its head is in Africa, where AIDs has devastated the population of the continent. In South Africa, for example, which has tended to be reticent about divulging its losses due to AIDs, the loss of life has been staggering. The *Washington Post* noted, “South Africa reported a 57 percent jump in deaths between 1997 and 2002, providing a startling—if indirect—picture of the rocketing toll of the country’s AIDs epidemic. Releasing figures from a widely awaited national mortality study, Statistics South Africa reported deaths had leapt to 499,268 in 2002 from 318,287 in 1997. Among those older than 15, deaths increased by 62 percent.”

The disease, which has completely changed the face of health in Africa, spread largely in the 1980s over the Trans-Africa highway, which had opened up vast areas of the continent to commerce. AIDs was carried over wide distances by truck drivers who passed it to roadside prostitutes, who were driven by rural poverty to the African cities that served the trucking trade, like Kinshasa in the Congo. Ironically,

in a situation where the ravages of AIDs are aggravated by the spread of modern commerce, the disease's toll is only made higher by traditional African tribal practices. In much of West Africa, tribal custom has held that abstinence from sexual intercourse marked the period after a wife gave birth to a child, a custom rooted in helping the new mother recover her health from the ordeal of child bearing. Of course, implicit too was that if she recovered in a healthy state, she would be able to bear more children to ensure the survival of the tribe. However, recent studies have shown that while husbands abstain from sex with their wives, they have sexual relations with other women, among whom there could be carriers of HIV, the virus which causes AIDs. In various studies, this situation was essentially unchanged after controlling for marriage type, age, education, urban-rural residence, income, and household wealth.

The report concluded with the observation that the potentially protective effect of prolonged abstinence after childbirth in Benin (and probably in much of West Africa) is offset by an increased probability that husbands will seek extramarital partners without using condoms. The implication is clear that to curtail new cases of AIDs, the old tribal customs will have to change and the population educated: What once helped the evolution of the species now hurts it. But such customs rooted in the past are difficult to alter. Thus, an ancient taboo, designed to promote the health of the mother and the ultimate survival of the tribe, has come to threaten tribal extinction from a modern nemesis: AIDs.

— John F. Murphy Jr.

EVOLUTIONARY PSYCHOLOGY

In *Evolutionary Psychology: A Primer*, Leda Cosmides and John Tooby write that "The brain is a physical system. It functions as a computer. Its circuits are designed to generate behavior that is appropriate to your environmental circumstances." During

recent years, this theory has led to a new trend in psychology and psychiatry: the use of new psychiatric medications. Increasingly during the 1990s and the early 2000s, Ritalin, or its generic form, methylphenedate, has been prescribed for the conditions known as attention deficit disorder (ADD) and attention deficit hyperactivity disorder (ADHD) among children, including elementary school age children. It was hoped that such medication would help to control or modify students whose behavior was considered disruptive to their teachers and classmates.

However, concern over the use, and possible misuse, of such a drug among young patients caused almost immediate concern from parents and medical personnel. The concern was underscored by the U.S. Congress Subcommittee on Early Childhood, Youth, and Families holding hearings on the subject in May 2000. Congressman Michael Castle, who chaired the hearings, noted in his opening remarks that "A news report on the increasing use of Ritalin caught my attention. I was particularly alarmed by the finding that for the years 1991 to 1995, the number of children ages two to four, who were prescribed psychotropic drugs, including Ritalin, increased by 50 percent. The researchers commented that these findings were 'remarkable' given the lack of research on the drug's effect on children." Such prescription of psychotropic medication also opened up another serious problem—those for whom the drug was prescribed were also selling it or giving it to their peers, either to increase performance in school or for recreational abuse.

The mounting concern over Ritalin and its possible abuses spurred further legislative attention, as legislators on all levels of government responded to the rising level of concern. The *State Health Lawmaker's Digest* for March 10, 2005, noted, "The results show that psychotropic medication prevalence varied across the three sites. Stimulant treatment in preschoolers increased approximately threefold during the early 1990s. During the late 1980s and 1990s, there was a dramatic increase in the use of psychotropic medications by children in the United States. This increase cuts across age, racial/ethnic, geographic, gender and insurance groups. Stimulants are often used as part of treatment for attention deficit-hyperactivity disorder (ADHD). Example: Ritalin."

One of the conclusions of the report was alarming: "Thus, there are still many unresolved questions involving the long-term safety of psychotropic medications in young children and the possible effects on a developing brain." While the debate over the use of stimulant drugs for the young continues, as does that for the prescribing of antidepressants, ongoing public interest ensures that the most important part of the dialogue will remain at center stage: the psychological health of young people.

— John F. Murphy Jr.

EVOLUTIONARY ONTOLOGY

Ontology is that branch of philosophy that asks what exists. Traditionally, this has been understood to mean what kinds of things exist in general, but in recent times, it has also been applied to mean what objects a scientific theory requires to actually exist if it is to explain the phenomena. We must therefore ask what things evolutionary theory requires to exist. This is, of course, distinct from the question of what things we can *observe* or *measure*, which is a matter of epistemology, not ontology.

In metaphysics, a distinction is sometimes made between *types* of things, and *tokens* of the types. A similar and related issue is whether things are *classes* that can be defined or *individuals* that can only be described or ostensibly defined (i.e., pointed at). Most evolutionary objects have been interpreted to be either types and classes or tokens and individuals. Part of the problem is that since evolution by definition involves a lack of stability in the objects it explains and covers, it is hard to clearly define the types of objects.

Universal Darwinism

Evolution is usually understood as a biological process, but following Richard Dawkins, and with antecedents well before him, attempts have been made to formulate what is called by Dawkins "universal Darwinism." This is a generalized model of evolution that is independent of the physical substrate—a kind of general theory of any possible evolutionary

process that might be called "Darwinian." Philosopher David Hull has applied it most extensively to the evolution of science, for example. We will consider biological evolution, but with an eye to the generalized ontological implications.

When we ask what "evolutionary theory" requires, of course we must take some representation of it, as that theory is itself evolving over time. The most widely discussed form is, of course, the conception of Richard Dawkins, sometimes called the "selfish-gene perspective," after his seminal book, or the "received view." Out of this and later works, a distinction was refined by David Hull, which has become known as the "Hull-Dawkins distinction," between *replicators* (genes and anything that is copied accurately like genes, including cultural items, called *memes*) and the economic systems they are part of and are reproduced when they are copied, which Hull calls *interactors* (organisms and anything like them that are differentially successful at getting the resources needed to replicate), although Dawkins prefers a less voluntaristic term, *vehicles*. Replicators are defined in Dawkins's *The Selfish Gene* as being those entities that are *fecund* (make more of themselves), *faithful* (have a high fidelity of replication), and are *long-lived* (persist over evolutionary time frames). Organisms do not persist over intergenerational time frames and so are not significant in evolutionary terms. Replicators are divided into "dead-end" replicators (for example, somatic genes), and germ line replicators (gamete genes).

The received view has been opposed or modified by critics, particularly Ernst Mayr (1988), who asserts that the objects subject to selection are organisms, not genes, which are "hidden" from evolution. Another critical stream is called "developmental systems theory," and its adherents hold that the evolutionary objects subjected to selection are *developmental systems* and life cycles. It is worth noting that Dawkins's view is a reworking and development of George C. Williams's notion of an *evolutionary gene*, which is, as he called it, a "cybernetic abstraction," defined as "any inherited information for which there is a favorable or unfavorable selection bias equal to several or many times its rate of endogenous change." A primary feature of evolutionary theory is that what is heritable, whether they are replicators or not, must have variant forms (in genetics, *alleles*) that can be in competition for resources in order for selection to occur.

Sewall Wright suggested a metaphor of an *adaptive landscape*, which is the fitness value of each possible allele of each locus in the genome. This is sometimes taken literally, as a description of the values of genes in an environment. The adaptive landscape is itself constituted by the states of other organisms and their genes, as well as by the physical environment in which all these organisms exist. The sum total of these features is called the *ecosystem*, which is arranged into classes called *ecotypes*. A particular role in an ecotype is referred to as a *niche*. These properties of evolving things are primarily economic; they refer to the physical resources required by interactors to persist until reproduction. William Wimsatt has influentially defined *reproducers* as the key object in evolution viewed from an economic aspect, instead of replicators. This has given rise to the distinction made by Stanley Salthe and Niles Eldredge between the *genealogical hierarchy* and the *economic hierarchy*. Genes apply only to the genealogical hierarchy.

Phylogenetic Objects

A major set of disputes has arisen over the *phyletic* (that is, the evolutionary-tree level) entities in evolution. These include questions about the ontological standing of *species* and other *taxa*, whether lower than species or higher. Mayr asserts the ontological primacy in evolution of the *population*, which is a group of interbreeding organisms, or a Mendelian gene pool. Populations are understood to be primarily statistical in nature, with properties distributed over modal curves. It is expected that most populations will be polymodal (in biology, *polytypic*). On this view, a species is the set of all populations (the *metapopulation*) that exchange genes. Asexual (nonreplicator exchanging) species have to be defined in another way, usually based on their genome clustering about a “wild-type” mode that is at an adaptive peak.

A somewhat different approach derives from the taxonomic discipline of *cladistics*. This approach of classification is by genealogy (*clades*, meaning branches) rather than by grades or overall similarities. The fundamental object of cladistics is the *lineage*, which is variously understood as a sequence of populations or as the parent-child relationship of any organic entity. Lineages that split (*cladogenesis*) form clades, which are the ancestor and all descendent lineages of a particular branch. Such groups of taxa are called *monophyletic* and are the only natural group

allowed in cladistic methodology. However, while clades are taxonomic groups based around species, cladistic methods also apply to genetic lineages, and the resulting trees of genes are considered to support phylogenetic trees if they agree. If they do not, a consensus of gene trees is held to give the taxonomic, or phylogenetic, tree.

Part of the problem with an evolutionary perspective for taxonomy is that the entities are not stable, and they are not all commensurate. While in the older Linnaean system, there were absolute ranks such as genus, family, order, class, kingdom, and so on, in the cladistic view, these are arbitrary and relative, and the only “natural rank” is the species, in part because the assignment of groups of species to these ranks is a subjective one. Cladistics is therefore a rankless system.

Beneath the level of species, there are smaller entities. In biology, there are subspecific groups known as geographical races, although the term *race* is now often avoided in favor of some other term, such as *variety*. Geographical groups are specified by a correlation of traits with distinct ranges. However, varieties can also be found across ranges, and in this case these are referred to as *subtypes*, *varieties*, or *trait groups*.

Group Selection

While the level of the individual organism (the interactor) is considered to be the primary focus of selection, another level is the *kin group*, in which the genetic fitness of a gene is the average fitness of all copies of the gene in all interactors (*inclusive fitness*). This allows selection to make individuals altruistic toward their kin, without making their genes less fit. However, it does not allow for altruism (in which a replicator makes its vehicle behave in ways that benefit other vehicles and not itself) to evolve toward nonkin, that is, those who do not share that gene.

Some have proposed *group selection*, in which the larger scale groups behave as the “fitness bearers.” Many think this is inconsistent with the replicator-interactor distinction or its precursors, while others seek to find analogues at higher levels to the canonical replicators and interactors. Group selection has been proposed for trait groups, temporary populations competing against each other, for species, and even for larger-scale clades. Even the classical argument of Williams against group selection allowed it could occur.

Some have also argued for the reality of *body plans*, or generalized structural arrangements of organisms, in evolution acting as constraints on the possible evolutionary trajectories in a “space” of morphologies (*morphospace*), although others consider this to be an artifact of the modeling methodology.

Ontologies and the Metaphysics of Evolution

Overall, evolutionary ontologies have been divided into those that are historical (process based) and those that are ahistorical (pattern based). Things that are defined ahistorically, such as some definitions of species, tend to rely on the characters or propositions used to define them. These things form *classes*, and they do not change, although a lineage might change into a class from another class or grade. A more recent approach is to see evolutionary objects as *individuals*, meaning not individual organisms or cohesive systems, but historical objects with a boundary in space and time. Michael Ghiselin and David Hull defined species as individuals in this way (although they have also defined species as cohesive individuals as well). Similar considerations apply to other evolutionary objects, such as genes; they can be classes on one account or individuals on another, but not both in the same account.

EXCAVATION

Excavation is one of the most commonly known and used techniques of archaeological investigation. It involves the systematic removal of data from the ground. Excavation provides the most complete evidence for human activity during a particular period and how these activities changed over time. There are many approaches to excavation, but at its most basic, the method involves looking at activities horizontally in space and vertically through time.

By its very nature, excavation is a destructive and costly process. It is an unrepeatable experiment that requires precise methods of data extraction and recording. Before excavating a site, it is essential to understand how sites are formed. Sites are what remains from settlements and other structures. The residues of a past social system will change over time due to decay, erosion, robbing, and the effects of plant and animal action. It is thus important to recognize these processes and distinguish them from the past actions that led to the creation of the site.

To understand this, it is essential to understand the principle of stratigraphy. This is a geological principle that states that layers of strata are laid down according to processes: The layer at the bottom is the oldest layer, while the topmost layer is the most recent. This is called the *law of superposition*. Understanding this process is crucial for interpretation and dating purposes.

The archaeologist, then, must carefully remove and record each layer and understand the stratigraphic sequence. He or she must be able to recognize how the process works. For example, a pit dug from a higher into a lower layer may lead to later materials being found in lower levels. Strata can also become inverted; for example, a series of strata can be eroded

to the bottom of a valley. To this, one must add what Michael Schiffer calls “N-transforms,” natural processes which affect the archaeological record, for example, burrowing by animals and seismic activity. Changes brought about by humans are called “C-transforms” (cultural transforms).

Sampling Strategies

The first requirement, however, is identifying the survey area in which to operate. Once that is accomplished, the archaeologist must then break down the region into smaller units in order to test the viability of any sampling strategy, particularly in little-explored areas. The major problem with this is in extrapolating whether the validity of results are representative of the survey region as a whole.

Such sampling techniques include systematic, random, and stratified random sampling. Systematic sampling can be thought of like alternating black-and-white pieces on a chessboard, which assumes that the sites themselves were laid out in a gridlike format approaching a modern city square layout. The pitfall is that the excavators may hit or miss everything if the layout of the site in question does not correspond to the idealized, superimposed excavation grid.

An alternative, random sampling uses a method whereby the sample squares in the survey region are fixed by randomly chosen coordinates. This method ignores known material culture distributions and environmental boundaries. While it might appear that such randomly chosen squares will be distributed widely, in practice, it is more common for tight clusters of squares to appear, leaving large sections of the surveyed region unsampled. Thus, this method does not take into account any knowledge of the landscape and the impact this may have had on the distribution of settlement and material culture remains.

As a result, the most commonly used sampling method is *stratified random sampling*. The survey area is first divided up according to its environmental or

Source: © iStockphoto/Tina Rencelj.

topographic layout, and sampling is then undertaken within each of the zones as deemed appropriate. This method has the advantage of combining ecological knowledge with the power of random test excavations.

However, even stratified random sampling has its problems. Although it attempts to balance statistical variability with representativeness, the region chosen for sampling is determined both by financial considerations and a degree of expectation on the part of the archaeologist about the nature and size of the site or sites expected. Therefore, the interplay between practical and theoretical considerations is a reflection of the research designs undertaken.

An example of good surveys is to be found in rock art studies. Many rock paintings are present in rocky terrain, which makes targeted surveying a necessity. Not all geological formations are suitable either for painting or for long-term survival of art, and field teams will normally focus on those geological zones that maximize the potential for mapping new occurrences of rock art sites.

Excavation Techniques

The focus on the methodology of excavations is far later in the history of archaeology. Early approaches simply involved the extraction of material deemed interesting by the excavator. While many such endeavors are accompanied by accounts, these are very different from the site reports familiar to students and archaeologists. The birth of modern techniques dates

to the 19th century. The British Lieutenant-General Pitt Rivers developed a precise methodology during excavations on his estate, Cranborne Chase. His meticulous attention to detail was simply groundbreaking.

Archaeological excavation methodology and its procedures are typical of sampling. Factors of preservation, together with the economics involved in setting up the research project, result in excavators adopting sampling procedures that are best targeted toward achieving the objectives of the mission.

Attention also is paid to other pragmatic considerations, like natural formation processes, as archaeological sites can have complex physical and organic environments. These include water and wind actions, animal depositions and interference, as well as plant growth. The impact of these actions could disturb the site in such a way that detailed reconstruction is required in order to interpret the original material traces in a meaningful fashion.

The reasons behind why a particular site was chosen to be excavated, and the manner in which it was, must be recorded. A test of good record keeping is replicability, which permits another archaeological mission to accurately track the steps taken by its predecessor and enables participants to access the excavation strategies employed and to reconstruct the contexts of the material culture unearthed. Although this attention to detail is important, as with all archaeological work, there is a continual interplay occurring between research aims, technical developments, and theoretical perspectives.

Vertical Dimensions

The interplay between cultural and natural formation processes, operating between when the site was first used and the time of excavation, potentially renders the stratigraphy of sites complicated. Repeated uses of a site by hunter-gatherers, for example, are difficult to separate out into their discrete visits. However, archaeological traces of fireplaces and food refuse are manifested through localized, subtle alterations in soil color. These are called *lenses*, which are present within the stratigraphic layer.

At sites that have been visited repeatedly for a lengthy period of time, it is often difficult to distinguish between the complex series of lenses and layers that develop. The archaeologist records such stratigraphies through the use of sections: the stratigraphy of a straight side in a designated trench.

In situations where there are no discernable differences in soil color or texture, the archaeologist still needs to maintain vertical control and therefore may elect not to try and excavate according to faint stratigraphic layers, but instead in arbitrary vertical units called “spits.”

Underwater Excavation

Horizontal and vertical control of deposits becomes even more paramount when dealing with sites under bodies of water; indeed, this is what distinguishes archaeological research from treasure scavenging.

Excavation underwater is rendered problematic by the presence of multiple hazards not encountered on the surface: seabeds of various textures exposed to currents, depth of sediments accumulated on top of the archaeological deposit, and the quality of visibility. Grid squares, made of rope, need to be placed over the designated area of the site and secured in place by concrete sinkers. Additional sinker markers are required for assisting in laying out the quadrants, which are buoyed and mapped using theodolites from the surface.

Thus, excavation techniques vary widely and are adapted according to the research requirements and the physical nature of the site in question. Despite the differing views held by archaeologists on the nature of the interaction between theory and data, the central tenet is to accurately establish the context in which the assemblages excavated occurred.

Stratigraphy as Dating

When deciding on what form of stratigraphic units to follow in an excavation, the archaeologist is also effectively deciding on the type of chronology to employ. Different, and sometimes discrete, human actions get compacted together by soil color and texture into layers. At Stone Age sites, many hundreds of individual actions and occupations may be compacted into a layer. Thus, archaeologists are confronted with the tangle of dealing with compacted human actions through artificially dividing the actions into discrete slices.

In this way, stratigraphy is at the heart of the archaeological concept of time, enabling reconstructions of chronologies to be undertaken through relative and absolute dating techniques. Examples of relative dating include analyzing and comparing the faunal compositions of neighboring or faraway sites,

constructing pottery seriation sequences, and more specialized techniques, such as contrasting the chemical composition of fossil bone material. Absolute dating techniques, providing age estimates that refer to a calendrical time scale, are based either upon radioactive decay or other natural processes.

Beyond Excavation

Excavation is the most visible part of archaeology. In the public mind, it is what archaeologists do. However, as any dig participant can attest, postexcavation is a far more time-consuming and equally important activity. Excavation is not meant to stand alone; the processing and publication of material is equally important.

Moreover, it is not always possible to fund excavation projects and/or obtain legal permits. For this reason, surveys have become increasingly important, for example, in the Mediterranean. While surveys potentially offer a broad range of information in a relatively shorter space of time, excavation remains the best way to uncover and document the past.

On another level, excavation provides an excellent opportunity to create dialogue with the nonarchaeological community. Ian Hodder's excavations at Catal Hoyuk are an example of reflexive archaeology and dialogue with various communities. Finally, the material culture recovered must be handled and conserved appropriately. Excavation also raises many contentious issues, including repatriation and claims to land rights.

EXOBIOLOGY AND EXOEVOOLUTION

Exobiology is the scientific search for life-forms existing elsewhere in this universe, whereas exoevolution involves speculating on the adaptive histories of organisms on other worlds.

It is not generally known that, at least once in his life, Charles Darwin envisioned the existence of plants and animals on another world. In 1836, having returned to a Brazilian rain forest and being impressed with its luxurious life-forms, he thought how great it would be if it were possible to admire the scenery of another planet. Darwin recorded this speculation in Chapter 21 of his first book, *The Voyage of the Beagle* (1839).

Do life-forms exist on other worlds? Are there intelligent beings living among the galaxies? Have advanced civilizations emerged elsewhere in this universe? These questions were asked by a few major thinkers in antiquity, but now these same questions are being taken seriously by many distinguished scientists and philosophers. The answers will have a direct bearing on the place life itself and the human species occupy within dynamic nature.

In particular, is the human animal unique and alone in this material cosmos? Or is the human species just one of many similar sentient beings inhabiting unknown worlds throughout sidereal reality? The science of exobiology intensifies human curiosity and challenges the imagination, while the quest to find forms of life and intelligence beyond the Earth requires a multidisciplinary approach that involves scientific specialists in various fields, from astronomy and biochemistry to biology and engineering, as well as the latest advances in space technology.

Exobiology

If life emerged from matter on the Earth, then is it not possible that organisms have appeared elsewhere in this universe? From ancient speculations to modern hypotheses, some of the greatest minds in the history of philosophy and science have grappled with the idea of exobiology (the existence of life-forms beyond this planet), for example, Cusa, Leibniz, and Kant.

In antiquity, Anaxagoras and Lucretius maintained that life does exist beyond the Earth. During the Italian Renaissance, the daring philosopher Giordano Bruno (1548–1600) argued for an eternal, infinite, endlessly changing, and inhabited universe. He even held that

intelligent beings, superior to the human species, exist on planets elsewhere in dynamic reality. Of course, his iconoclastic framework challenged the earthbound and human-centered worldview entrenched in Western philosophy and theology. In fact, Bruno was burned alive at the stake in Rome (near the Vatican) because of his unorthodox worldview.

In the 20th century, although a silenced evolutionist, the geopaleontologist and Jesuit priest Pierre Teilhard de Chardin (1881–1955) failed to take seriously the probability of life-forms and intelligent beings existing on planets elsewhere. Instead, he focused on this Earth and the human species. Actually, his cosmology is merely a planetology. In his major work, *The Phenomenon of Man* (1955), Teilhard believed that the final goal of human evolution is a spiritual Omega Point at which time the united human species will merge with a personal God at the end of Earth history in terms of a converging and involuting collective consciousness. It is not surprising that his mystical vision satisfied neither religious creationists nor scientific evolutionists, although the courageous Teilhard is to be greatly admired for his serious introduction of the fact of evolution into modern theology.

Going beyond the ideas of Galileo and Darwin, one may anticipate an exobiology revolution in scientific cosmology. The impact would be awesome for the human species. No longer would the Earth or the organisms on this planet, including humankind, be unique in this universe.

In the United States, astronomers Frank Drake and Carl Sagan took the emerging science of exobiology seriously. In 1961, Drake proposed a mathematical equation to determine the number of detectable civilizations in this universe. His calculations suggest that there may be thousands of civilizations similar to those of humankind in the Milky Way galaxy. And in his popular writings and television series, Sagan brought the exciting probabilities of exobiology to the general public. Modern technology now makes the search for life and intelligence elsewhere possible, particularly in terms of space probes and radio telescopes, for example, the Arecibo Observatory in Puerto Rico.

Concerning civilizations with advanced technologies, physicist Freeman Dyson speculates that superior beings could use planetary matter to build an energy-capturing sphere (“Dyson Sphere”) around their star.

In Russia, the scientists Nikolai S. Kardashev and Iosif Shklovskii have proposed the construction of

several huge radio telescopes in the Earth’s solar system, in order to detect extrasolar planets. Actually, modern astronomers have already discovered over 60 planets existing in other solar systems. Kardashev has classified civilizations into three energy output types: Type 1 is planetary, Type 2 is solar, and Type 3 is galactic. Going beyond this scheme, one could even imagine a supercivilization utilizing the power output of a cluster of galaxies.

Considering the age and size of this expanding universe, with its billions of years and billions of nebulae, there has probably been all the time and space necessary for life (as now known) to have emerged more than once in nature. The general uniformity of both physical laws and chemical elements throughout reality increases the probability that life, that is, the RNA or DNA molecule, has appeared on other worlds. In fact, carbon and water are plentiful in this universe. Furthermore, organic molecules (amino acids) exist in comets, meteors, cosmic gas/dust clouds, and planetary atmospheres. Therefore, the conditions for the origin of life do exist elsewhere in reality. Surely, the discovery of the RNA or DNA molecule in the sidereal depths of outer space would give exobiology an empirical foundation it now lacks, and it would intensify further scientific investigation for conscious observers and intelligent machines elsewhere in this cosmos.

All living forms need not be restricted to only this planet. Because there are billions of galaxies, each with billions of stars, it seems reasonable to assume that there are millions of solar systems with planets similar to the Earth. No doubt, at least some of these planets would resemble the Earth in size, chemistry, temperature, and atmosphere. Thus, it is highly probable that zones with the necessary conditions for the origin of life exist elsewhere. Of course, extraterrestrial organisms need not be similar to those plants and animals that have inhabited and now exist on the Earth. As a result, alien forms of galactic life could be so different from known organisms that they may not be recognized by the human species or detected by its technology.

Is life a unique miracle or random accident or statistically inevitable, given enough time and the right situation? Actually, the origin of life on this planet was remarkably swift from the geological perspective. It appeared about 4 billion years ago, only 600 million years after the formation of the Earth. Surely, if the origin of life happened once, then it can happen again elsewhere under similar conditions; recall that the prebiotic chemistry for life pervades this universe.

Logic does not dictate that this planet or life on Earth or the human species must be unique in all reality (although religionists and theologians may still believe each of these claims to be true).

At this time, there is no direct empirical evidence to support exobiology. Because of the awesome cosmic distances among the stars and nebulae, one may never discover the existence of life on other worlds in this universe (even if it does exist). Life-forms may have emerged and vanished before the existence of this solar system, or organisms will appear on other planets in the remote future. Another possibility is that superior beings elsewhere may not be interested in the human species; if they are intelligent enough to discover humankind, then they are wise enough to stay away. The human animal has nothing to offer such superior visitors from deep space.

Furthermore, it is possible that other universes with life-forms have existed before this one, are coexisting with this world, or will exist after this particular cosmic epoch has ended. Consequently, the questions raised by exobiologists may never be answered in the affirmative, even if life does exist elsewhere. The same is true for questions concerning exoevolution.

Perhaps numerous inhabited planets do orbit stars in this galaxy and in others. Concerning the organic evolution of life-forms on other worlds, what is possible? If planetary systems are common, then do Earthlike worlds elsewhere harbor biological activity needing carbon and liquid water (or is life elsewhere based on another element, for example, silicon or boron)? The human quest for cosmic life and intelligence may even find fossils and artifacts on other worlds.

Exoevolution

Four billion years of biological evolution on this planet have produced a staggering spectra of organisms, ranging from bacteria and plants to invertebrates and vertebrates. This creative unity of global life includes such diverse life-forms as worms, sponges, sharks, turtles, snakes, and elephants. Among the very social creatures are species of insects, birds, and primates (especially the pongids and hominids). Yet, most of the species that have inhabited this world are now extinct, for example, all the trilobites, ammonites, and dinosaurs have vanished from the biosphere.

As if organic evolution on Earth is not difficult enough for many to accept, especially biblical

fundamentalists, then the discovery of exoevolution will challenge all thinkers to seriously reassess the place that humankind occupies in dynamic reality.

The only process of organic evolution that is now known to science is the one taking place on Earth. However, exobiology infers exoevolution. Environments are never fixed anywhere in nature. No doubt, the struggle for existence pervades this universe. As on this planet, life-forms elsewhere would have evolved to meet the challenges of their changing habitats. One can only speculate on what directions organic evolution and adaptive radiation have taken on other worlds. Perhaps human explorers will find species similar to ants, whales, and the apes; and maybe even the technological remains of past civilizations, or the existence of cognitive biorobots of superior intelligence, will be discovered in this cosmos.

If life-forms are found elsewhere, then future scientists and philosophers would participate in the critical study of comparative exoevolution. Or if human beings send themselves and other life-forms into outer space, then these plants and animals will evolve in strange new habitats (thereby making the study of exoevolution a certainty). In fact, the human species itself may evolve into a new form of life as it adapts to living among the distant stars.

Are we completely alone in this material universe? If not, then contact with extraterrestrials will be the most momentous event in human history. In fact, the Nietzschean Overman may have already emerged somewhere in this universe. Cosmic aliens with superior intelligence could be wise, benign, creative, and compassionate, or they could be indifferent and evil. Certainly, their achievements in science and technology will be far beyond our comprehension.

Moreover, cosmic microbes may cause diseases that could bring the human species (if not all terrestrial life-forms) to extinction. The cosmic quest for life elsewhere is not to be taken lightly.

Exobiology and exoevolution directly challenge geocentrism, zoocentrism, and anthropocentrism. The discovery of organic evolution beyond the Earth will make this planet and the human species even less significant than they now are. If intelligent beings are discovered elsewhere, then the human animal will no longer be something special in this universe. Such an incredible event would have an awesome and lasting impact on humankind's science, philosophy, and theology (not to mention the inevitable psychological and sociocultural changes to the self-centered human

species). Giving priority to science and reason, and with courage and humility, future naturalists will need to accept the true place of our human species in material reality from a cosmic perspective and within the evolutionary framework.

For most scientists, the origin of life on Earth was a strictly materialistic event. The subsequent history of living forms on this planet has been a long, complex, contingent, unpredictable, opportunistic, and inefficient process of biological evolution. Organic evolution is also nonrepeatable, irreversible, and subject to material constraints.

Homo sapiens sapiens is a product of, dependent upon, and totally within evolving nature. Because of the staggering necessary sequence of improbable events that had to occur in order to bring human beings into existence, it is unlikely that the human species will meet its exact duplicate on a remote world. Nevertheless, at least once, with the recent emergence of the human being, this dynamic universe became aware of itself.

Rational speculations are very important, but there is no substitute for evidence, observation, and communication. It is conceivable that processes of evolution elsewhere in this universe have produced forms of life similar to, or remarkably different from, those species that have emerged on the Earth over billions of years. In fact, the possibilities for life-forms inherent in exoevolutions on other planets seem endless.

Of course, extinction and evolution are two sides of the coin of life. A comet strike or global plague or nuclear war could wipe out the human animal and most, if not all, of the other species on Earth. In fact, this vulnerable planet has already experienced at least five mass extinctions. Similar horrific events may have already eliminated all life-forms on some other worlds.

There is no evidence of a preestablished direction or preconceived purpose or preordained goal for this cosmos that gives the human species a central position in material nature. This universe is clearly independent of and utterly indifferent to humankind; until now, the human species has played no special role in the existence of reality. There was cosmic time before the appearance of the human animal, and material nature will endure after the extinction of life and consciousness on this planet.

At some time in this millennium, reminiscent of the young Charles Darwin in a Brazilian rain forest, a naturalist may stand on another world and marvel at forms of life beyond humankind's present imagination. Another intriguing possibility remains: the survival

and fulfillment of the human species may depend on its working in consort with sentient life-forms still to be encountered elsewhere in this universe.

From the Greek ἐντὸς + γαμῶ (“out” + “to marry”), exogamy is the marital rule according to which the spouse must be sought outside the social group (e.g. kindred, totem, royal) one belongs to. It is the opposite of endogamy.

The explanation of exogamy has been a major concern for anthropologists. In addition, as it has been mainly linked to the interdiction of incest, which constitutes the most important form of exogamy, exogamy as a social phenomenon was considered to

be of natural origin. However, Lévi-Strauss theorized that the interdiction of incest, and therefore exogamy, is not of natural but of cultural origin. Based on a quote from Tylor, he proceeded to give the succinct interpretation that man very soon realized that he needed to choose “between marrying-out and being killed-out.” Under these conditions, no society can exist without exogamy.

Just as social groups aim to preserve and transmit their constitutive elements (for example, power, wealth, religion, language) to the following generations through endogamy in order to perpetuate their existence, exogamy aims at forming alliances between the groups connected through marriage for the same purpose. This perpetuation is achieved as well through biological replenishment as well as any sort of strengthening (financial, military, etc.) and the resolution of enmities, and so on, as has been and is the case with royal families, for which exogamy is the norm. An example of this is the marriage of Eric Tudor, heir of the house of Lancaster from his mother’s side, with Elisabeth from the house of York. Eric was crowned king by setting an end to the War of the Two Roses (1455–1458), fought between the houses of Lancaster and York over the throne of England. The war took its name from the crests of the houses, Lancaster’s being a red rose and York’s a white one. With his marriage, Eric united the two roses on his crest and became the head of a new dynasty.

Consanguinity Kindred Exogamy

The most common form of exogamy occurs with the selection of the spouse outside the kindred group within which marriage would constitute incest. The stringency of the universal rule forbidding incest (and thereby enforcing exogamy) varies for different societies, ranging from the interdiction of marriage between parents and children as well as between brothers and sisters to the interdiction of marriage if even a single common ancestor is discovered.

For instance, the Greek Orthodox Church allows marriage between relatives beyond the fourth degree (i.e., the first cousins) for consanguinity kindred. However, custom appears to be stricter than religion, as it only allows marriage between relatives past the second cousins most of the time, or even past the third cousins on more rare occasions. Elsewhere, as in for example, the Aborigines in Australia, marriage is forbidden between parallel cousins, that is, children

of two siblings of same sex, which are considered to be siblings (a case of exogamy). Conversely, it is allowed and even largely enforced between cross cousins, that is, children of two siblings of different sex (brother and sister), this being a case of endogamy.

Lineage and Clan Exogamy

Exogamy is also a very frequent phenomenon on a *clan* (a social group the members of which acknowledge a common ancestry and whose relationships are ruled by solidarity) or *lineage* (the group of individuals who are interconnected through consanguineal kinship either patrilineally or matrilineally and who acknowledge a common ancestor) level. In northern Albania and parts of southern Albania, the *fis*, a large group of men of patrilineal descent with a common ancestor (lineage), follows a strict exogamy. The obstacles to marriage derive from the state of consanguinity the members of the same *fis* share because of their “blood link,” originating from their patrilineal affiliation. If a marriage within the *fis* was discovered, the “culprits” were subjected to persecution and could even be assassinated. The *clans* in southern Mani (Greece) were also exogamic for the same reason.

A strict exogamy is obeyed by most totem *clans*, that is, clans bearing the names of plants, animals, or natural processes that they usually treat as their ancestors and protectors (totems). The members of the clan with this common ancestry consider each other relatives. This results in exogamy, as in the Ojibwa Native North Americans, where the term *totem* originates (*ototeman* means “is my friend or relative” in their language).

Fictitious (or Ritual) Kindred Exogamy

Apart from consanguineal (or by affinity) relatives, individuals related by *fictitious* (or *ritual*) kinship are also usually subject to exogamy. This term covers social bonds equivalent to consanguineal or affinity kinship, often using the terminology of kinship (or cognate terms, for example, father-godfather) and usually necessitating a ritual for their creation (such as godparenthood, adoption, or fraternization).

The rule of exogamy is thus particularly stringent for godparenthood in the Greek Orthodox Church, where marriage is forbidden between the godparent and the godchild as well as the godparent and the godchild’s parent. This is because the godparents are considered to be spiritual parents and the godchild

their spiritual child. In order to remove the risk of such a marriage, custom dictates that men only baptize boys and women only baptize girls. This practice has yet another purpose: it eliminates the possibility of a marriage between godchildren baptized by the same godparent. The godchildren are considered siblings by custom and for whom marriage is forbidden. The danger of a marriage of this kind is particularly evident in endogamic societies. Still according to custom, marriage is also forbidden between the natural children of the godparent and their godchildren, who are considered siblings as well.

Exogamy usually applies between an adopting parent and an adopted child in most societies, as the adopted child takes the place of a natural child. In some cases, for example, in Albania, a powerful *lineage* could adopt a weaker one by adopting one of its children. The members of both lineages would then be subject to exogamy.

Interdiction of marriage also stands between individuals who have become siblings following a ritual (fraternization), although these individuals are most often of the same gender (usually men). Fraternization is encountered in many African and Balkan societies, where exogamy can apply to the families of the individuals linked by fraternization and often to the members of both their lineages.

EXTINCTION

Extinction is a word commonly associated with undesirable, catastrophic loss of entire populations or

species. However, extinction is as much a part of the cycle of life on Earth as is evolution. Indeed, extinction and evolution together form the cycle responsible for the ever-increasing complexity of life on Earth. From the earliest evidence in the fossil record, we see populations and species disappear, to be replaced by other populations and species. In most cases, this occurs as the more complex organism replaces the simpler one. However, there have been several times in the Earth's history when mass extinctions occurred that wiped out the complex forms but allowed simpler forms to survive.

It is human nature to seek ways to forestall or avoid the inevitable concerning human extinction, and thus the study of extinction has earned high priority in scientific circles. This heightened interest has led to significant research on the topic. A true understanding of the processes of extinction requires a detailed understanding of most facets of the Earth's history, including climate shifts, tectonic movements, atmospheric conditions and content, sea level changes, and the flora and fauna itself. The geologic and fossil records are notoriously incomplete, making this research difficult. Even the tidbits that have been discovered, however, provide tantalizing glimpses into the intricate and complex patterns and processes of extinction.

Extinction can best be defined as the condition that exists when the last remaining individual of a population or species dies. Since this death can be caused by any number of factors and since extinction is inevitable for every species on Earth, understanding the causes, patterns, and processes involved can be daunting.

Types of Extinction

Extinction events can generally be divided into two types: background extinction and catastrophic, or mass, extinction. Background extinction follows the concept of Darwin's "survival of the fittest," perhaps better expressed as "survival of the luckiest." For one reason or another, groups of living organisms regularly pass into oblivion. These reasons include lack of nutrients, disease, genetic anomalies, unusual weather conditions, and being out-competed for existing resources. Changes in climate seem to play the largest role in this type of extinction. Very minor changes, as small as having a drought in a region for a few years, can cause an extinction event.

Background extinction seems to be part of a cycle most species of organisms follow. Initially, a species comes into existence from organisms occupying a new environment or following a new life style compared with their ancestors'. These organisms typically exhibit few specializations, and they are generally not very well suited to the new environment or lifestyle. Through successive generations, the organisms become more specialized and better able to exist in the new environment, but this comes at the cost of being less able to cope with changes to the new environment. Finally, the organism faces the problem of a change in its new environment, and because it no longer has the ability to adapt and change rapidly, it dies out. If the species is not an evolutionary dead end, somewhere in this process, some of the offspring were either born defective, forcing them to move into a different environment to survive, or perhaps a small group was merely trapped in an area where the environment was somewhat different. In any case, the demise of the parent species leaves behind one or more daughter species, and the cycle continues. Throughout the history of the Earth, this pattern has produced a gradual increase in both the number of different species and the complexity of organisms on Earth.

Catastrophic extinction often has the opposite effect on the number and complexity of Earth's species. Catastrophic extinctions, as far as is currently known, are always related to a massive, rapid change in the Earth's global environment. Such extinctions tend to affect the most complex and specialized organisms more rapidly and seriously. Simpler, generalized forms are usually better able to survive catastrophic events. There have been numerous catastrophic extinction events throughout Earth's history. Although there are many references to the "Big 5" and the current extinction as the sixth, there have actually been more than 20 times when mass extinction has occurred. Catastrophic extinction is defined as the extinction of a large number of species in a short time interval. It is easy to see that extinction events may be included or excluded from this category based simply on what one decides is a "large number of species" and a "short time interval."

There have been at least 5 major catastrophic extinction events and at least 14 more events that saw losses of more than 20% of species of organisms on the Earth. In addition, there may be as many as a dozen more extinction periods in the fossil record that are potentially this severe. However, due to the incomplete nature of the

rock and fossil records, these events may or may not have occurred, and the actual number of Earth's catastrophic extinction events may never be known. Also, the classification of extinction events is arbitrary; there are no sharp separations in severity of extinction events. Extinctions of virtually every resolvable magnitude have occurred, from one species to virtually all species wiped out in a single event or time period.

Benefits of Extinction

Most of the research concerning extinction is concerned with the harmful effects to living species and the best means of preventing their extinction. A major force in human politics today is maintaining the current "status quo." Humans do not like to see change, especially when it concerns the loss of species that humans value. However, the history of hominids would be quite different were it not for the driving forces of extinction and adaptation. The last few million years of Earth's climate history have been unusually variable. The Earth has gone from very warm to very cool several times during this period. We are currently experiencing a moderate global temperature that is unusual from a geologic perspective. In fact, scientists are divided over whether we are on the brink of another ice age or a severe greenhouse event.

Such fluctuations of global climate have undoubtedly been responsible for the "weeding out" of hominid species such as *Australopithecus* in favor of the more intelligent *Homo habilis*. Had the climate not changed and the forests of the Pliocene given way to savannah grasslands, the australopithecines would likely still abound. The global cooling of the climate during the early Pleistocene caused the loss of the forest habitat of *Australopithecus*, and the species most likely died out as a result of this loss of habitat. However, the ability to use tools and the addition of meat to the diet allowed at least some members of *Homo* to survive and thrive long after the extinction of *Australopithecus*.

Similar climatic variation throughout Earth's history is likely the single most important mechanism behind the evolution of increasingly more complex species. An event that spells disaster for one population or species is likely to provide an opportunity for another group to change, adapt, and grow. From the current data, it seems that only the most cataclysmic events in Earth's history reverse this trend and cause the loss of the more complex species.

Major Extinction Events

The earliest-known, well-documented catastrophic extinction occurred near the end of the Precambrian, approximately 670 million years ago. This event wiped out approximately 70% of Earth's species; stromatolites and acritarchs were especially hard-hit. This extinction likely produced the conditions needed for the Vendian fauna, a series of soft-bodied animals, to appear and evolve. In turn, the Vendian fauna were largely wiped out approximately 520 million years ago, and the Cambrian hard-shelled fauna appeared. Other events documented by major faunal turnovers include the end-Cambrian (488 mya), end-Ordovician (438 mya), late Devonian (360 mya), end-Permian (251 mya), end-Triassic (200 mya), end-Cretaceous (65 mya), and end-Pleistocene (the last 10,000 years).

Five of these extinction events have been recognized as the "Big 5": the late Ordovician event, when 84% of animal species went extinct; the late Devonian extinction, when 79% of existing species were lost; the end Permian extinction, when over 95% of all species died out; the late Triassic extinction, when 79% of species vanished (this actually turned out to be two closely timed but separate events; however, it is still considered one of the "Big 5"); and the Cretaceous Tertiary (K/T) extinction, which ended the reign of the dinosaurs and over 70% of animal species disappeared. It is likely that more taxa were lost from the Vendian and Cambrian extinctions than from some of the "Big 5" events, but the paucity of the fossil record prevents truly accurate determinations. Also, please note that the numbers of missing species supplied here are calculations and estimates from studies mostly concerned with hard-shelled invertebrates. Other organisms either preserve poorly (small vertebrates, soft-bodied invertebrates, unicellular and colonial organisms) or are primarily nonmarine (plants, higher vertebrates) and thus are preserved only under fortuitous circumstances. These factors severely limit the accuracy of the numbers listed above but should not significantly affect the relative severity comparisons.

The most severe extinction event was the Permo/Triassic (P/T) extinction. It is estimated that the Earth was virtually sterilized at that time, with over 99% of all life being wiped out. Because it takes only a small surviving population of any taxon to preserve that taxon, the extinction percentages are largest at the lowest taxonomic levels. For instance, over 99% of individuals were lost during the Permo/Triassic event, but only 95% of

species, 70% of genera, and 50% of family-level taxa were lost. It should also be noted that such a massive disruption to global ecology is also seen in the rocks themselves. The Paleozoic rocks of the world are noted for their abundance of marine, coral reef structures, and even amateur geologists easily recognize the red sandstones of the early Triassic in outcrops around the world. Only one family of coral survived. There has not been one fossil reef structure found in rocks dating to the first 10 million years after the Permo/Triassic extinction event, and it took 100 million years for corals to again create significant reefs worldwide.

Causes of Extinction

Causes of catastrophic extinction, except in the current instance, are speculative at best. One observation that has troubled researchers for a long while now is the periodicity of extinctions and how this periodicity may correlate with astronomical events. There seems to be statistically significant regularity in the timing of extinctions, and this observation has spawned several hypotheses concerning causes for increased large meteor, asteroid, or comet impacts during those periods. As of this time, there is no conclusive evidence of this being the case, but the hypothesis does coincide with the K/T extinction being caused by asteroid impact. Unfortunately, the cycle is 26 or 27 million years in duration, and most evidence of impacts vanishes in only a few thousand years due to erosion and redeposition. Most recently, this line of investigation has led to the suggestion of a hypothetical binary sun (Shiva or Nemesis) or 10th planet (Planet X) that has an orbit that passes through the Oort Cloud, disturbing orbits and sending an increased amount of comets and other objects hurtling toward the Earth. It is well documented that a magnetic anomaly affects Uranus, Neptune, and Pluto, and this is the primary evidence that some large celestial body exists in the distant reaches of our solar system. Without precise measurements of this object and its orbit (its very existence is conjectural at this point), its effect on other objects in our solar system is impossible to accurately predict.

There are, however, several well-documented causes of worldwide catastrophe that don't involve a hypothetical planetary body. Every major extinction event and most of the minor ones have been associated with one or more known climate-altering events. In fact, of the "Big 5," all but the late Ordovician

extinction are time equivalent, with massive extrusive volcanics and large meteor craters. Also, all of the “Big 5” are associated with large-scale glaciation except the K/T event. Trying to sort out the relative importance of these factors contributing to Earth’s extinctions has been the focus of much research, speculation, argument, and frustration. It is likely that every major extinction event involved a variety of factors that combined to create inhospitable, often uninhabitable, environments over large portions of the Earth’s surface.

It is now known that many of the recorded extinction events are correlated with changes in sea level. When glaciers cover significant portions of the Earth, virtually all continental shelf environments are brought to the surface, severely reducing the amount of available primary marine habitat. Likewise, when sea levels rise, major portions of the most habitable continental lowlands are inundated. This rise and fall of sea level is largely responsible for most documented extinctions, because the preserved sediments are primarily marine and show the loss of these types of life. Sessile organisms abound in continental shelf environments, but they are very susceptible to extinction through loss of habitat. It is possible that current research is skewed in overreporting (or underreporting) the seriousness of an event because most of the data gathered to date are from these marine environments.

The Current and Future Extinction

Compared with past extinction events, the current rate of species loss is very high. Should this rate continue for more than a few thousand years, the current event will easily rival the “Big 5” when it comes to number of species lost. However, it is beyond human experience to be able to recognize if this loss is comparable to other minor events or if it is truly a major catastrophe for life on Earth. The fossil and geologic records provide us with glimpses in time, but the records are of instants that are usually hundreds or thousands of years apart. If we were looking at the fossil record of this time from the vantage point of several million years in the future, we would not be able to separate those species lost during the last ice age from those lost last year.

The one comparison that can be made is how, in general terms, the current conditions on Earth match up with conditions during, or just prior to, any other extinction event. The Earth is recovering from an ice

age, which matches the conditions found at the onset of at least four major extinctions. This is significant in that every documented ice age event is observed to coincide with an extinction event, and ours is no exception. When combined with a dramatic rise in temperature, as in a virtually instantaneous global-warming event, the matching situations found in the geologic record indicate a severe extinction. This, in fact, was the situation that was thought to have existed at the time of the P/T extinction event.

Unlike the P/T event, however, the Earth is not currently experiencing massive volcanic eruptions, nor is the Earth experiencing sizable asteroid impacts. Should both of these events happen, the Earth would undoubtedly see a repeat of the P/T extinction and most life would cease to exist. On the other hand, the P/T event was mitigated somewhat by the amount of carbon removed from the system through the reef-building processes of the Paleozoic. The Earth is currently experiencing a reintroduction of massive amounts of carbon previously removed from the system, and this is creating a carbon overload and atmospheric carbon dioxide spike.

On the whole, many scientists see many similarities between the Earth’s final minutes before the P/T extinction and the present. The two questions, “Do we need to stop this pattern?” and “Can we stop this pattern?” are likely to plague scientists for the foreseeable future. Unfortunately, the answers to these questions may determine the cause and severity of the next extinction event on Earth.

MASS EXTINCTIONS

The earth has an enormous biodiversity. However, many scientists, biologists, oceanographers, zoologists, and numerous others who work in scientific disciplines are very concerned that the earth may soon experience a catastrophic loss of a great number of species.

There are an estimated 2 million plants and animals known today. Some scientists estimate that as many as 50 times that number may exist. However, the danger is that a great number of species may disappear before they are even discovered.

There is geological evidence from fossils that during previous geological eras many species vanished within a short period of time. There may have been as many as five major extinctions that occurred during the earth's history. Fossil evidence strongly suggests that massive dying of species occurred during the Ordovician, Devonian, and Permian geological eras. The most obvious example is the disappearance of the dinosaurs. However, the

concern today is that another "great dying" of species is being caused not by nature but rather by humans.

Polls taken of biologists, environmentalists, naturalists, and other scientists report concern not only that numerous species are now threatened with extinction but also that a massive extinction is under way. Some have estimated that 20% of all species could disappear by 2040. The estimate of extinction by some scientists is as high as 50,000 species each year.

The single major cause of massive species extinction is widely believed to be human activities. These activities include the thinning of the ozone layer, global warming, hunting, farming, mining, pollution from industry, deforestation and logging, the introduction of invasive species, habitat loss, and degradation. Evidence for species extinction that scientists offer includes the great declines in populations of plants, fish, and frogs as well as the decline in living corals in coral reefs.

The International Union for Conservation of Nature and Natural Resources is a global organization networking thousands of scientists. It has issued a "Red List" of species that are extinct, threatened, or endangered as well as those that are in satisfactory condition.

Critics charge that the claims of massive extinction are exaggerated and alarmist and that these overestimations are falsely derived from extrapolations based on the destruction of rain forests or other rich habitats. When asked in opinion polls, many laypeople do not believe that mass extinctions are likely to occur.

FA HIEN CAVE

Human skeletal remains of Late Pleistocene antiquity were recovered from several caves and open-air sites in Sri Lanka during the last half of the 20th century. Fa Hien Cave is one of the largest on this island nation and is situated in the southwestern lowland wet zone of Katutura District, Sabaragamuwa Province. In 1968, human burials were excavated by Dr. Siran U. Deraniyagala, of the government's archaeology department, and 20 years later, with his assistant, W. H. Wijepala. These archaeologists dug in two areas at the center and rear of the cave, which yielded at the lowest level above the bedrock numerous stone non-geometric microlithic tools, charcoal from ancient hearths, and faunal and human skeletal remains. Radiocarbon dates obtained from charcoal at this first level and at deposits above it indicate that Fa Hien Cave was occupied over a long period of time: from about 33,000 to 4,750 years ago. This time frame embraces the Late Pleistocene and Early to Middle Holocene epochs. The human bones from all levels were removed from their burial deposits and transported to the Human Biology Laboratory at Cornell University, Ithaca, New York, where they were examined by Dr. Kenneth A. R. Kennedy and a graduate student, Joanne L. Zahorsky.

The most ancient skeletal series consists of fragments from several individuals, including a child of 5.5 to 6.5 years of age, two infants, a juvenile, and two adults. Their bones are coated with red and yellow ochre. Cranial and postcranial bones indicate they are secondary burials; that is, following the death of these individuals, their survivors exposed their bodies to the elements. During postmortem decomposition, scavenging animals and climatic temperature changes reduced the bodies to bones. These were later collected

and deposited in the graves from which the archaeologists exhumed them. Deposits nearer the present ground surface of the cave floor include skeletal remains of a child and a young adult female dated circa 6,850 and 5,400 years ago, respectively. These, too, are secondary burials, with the bones coated with red and yellow ochre.

Given the fragmentary condition of the cranial and postcranial bones from all of these human remains at Fa Hien Cave, laboratory examination focused upon the teeth, many of which are well preserved. Deciduous and permanent teeth were measured, and their mean crown diameters and robusticity values were compared with a large number of other prehistoric and modern human populations for which dental data have been published. Results of this study show that the dentition reveals relatively large molar tooth size for all specimens, the deciduous molars of infants and children being larger than deciduous molars of later prehistoric populations and modern humans. Since all of the teeth exhibited extreme wear on their occlusal surfaces, it appears that large tooth size was adapted to a coarse diet impregnated with grit and sand from grinding nuts, seeds, and grains in stone querns and other food preparation techniques. A trend toward tooth size reduction in hominids was a consequence of plant and animal domestication that began at the beginning of the Holocene epoch, but Sri Lankan populations continued a hunting-gathering socioeconomic lifeway until the beginning of its Historic period, around the 8th century BC.

Fa Hien Cave is important to archaeologists and human paleontologists because its earliest people were contemporaries with Cro-Magnon populations in Europe and other Late Pleistocene hominids of Europe, Africa, Asia, and Australia. But Fa Hien Cave is not the only prehistoric site on the island that has been excavated and yielded human skeletal remains.

Geometric microliths with human bones and teeth occur in the same southwestern sector of the island at the cave sites of Batadomba Lena (ca. 28,500 years ago) and Beli Lena Kitulgala (ca. 12,000 years ago), and at the open-air site of Bellanbandi Palassa (ca. 6,000 years ago). Sri Lanka has the earliest-dated microlithic stone tools in the prehistoric record, and on the adjacent Indian mainland, this technology does not appear in archaeological sites until the Early Holocene epoch. These stone tools are first present at about this same time in Europe, although geometric microliths have been recovered from Late Pleistocene sites in sub-Saharan Africa. Later cultural traditions of the Sri Lankan Iron Age flourished by the 7th century BC, with its hallmarks of iron weapons and implements, the construction of megalithic monuments, and unique ceramic vessels. It has been proposed that the aboriginal people of Sri Lanka, the Veddahs, show some cranial and postcranial anatomical similarities to the later microlithic-using inhabitants of the island.

FAGAN, BRIAN M. (1936–)

Brian Fagan (b. 1936) is arguably one of the world's most influential archaeologists, in that he has reached thousands of archaeology students through his college-level archaeology textbooks and millions of nonarchaeologists through dozens of popular archaeology books and articles. The son of a publisher, Brian Murray Fagan was born in Birmingham, England. After 2 years in the Royal Navy (1954–1956), he was admitted to Pembroke College, Cambridge, where he studied Stone Age archaeology and earned a bachelor of arts with honors in 1959, a master of arts in 1962, and the PhD in 1963.

Fagan's professional career began in Africa as Keeper of Prehistory at Zambia's, then Rhodesia's, Livingstone Museum. While there, Fagan excavated the Acheulian components at Kalambo Falls and reorganized the museum's archaeological collections; the former was the basis of his 1963 PhD dissertation. Fagan held this position until 1965, when he left to become the director of the Bantu Studies Project for the British Institute in Eastern Africa. Shortly thereafter, after tiring of fieldwork, Fagan accepted a visiting scholar position at the University of Illinois in Urbana-Champaign. In his 2004 retrospective, he described his experience at the University of Illinois as "severe intellectual shock," as he came face-to-face with what would come to be known as the "New Archaeology" and with the realization that he had missed nearly a decade of archaeological

literature. The following year, Fagan joined the Department of Anthropology at the University of California in Santa Barbara, where he served in a variety of faculty and administrative roles. Fagan retired from the University of California in 2003 as professor emeritus, after 36 years of teaching, research, and service.

Although much of Fagan's early career was committed to research, mainly in Iron Age Africa, he is best known for his commitment to bring archaeology to the public through the publication of numerous books, magazine articles and columns, television and radio documentaries, and, recently, interactive multimedia formats. Fagan's interest in popular nonfiction was inspired by his archaeological research in Zambia, where he was writing history literally from the ground up, since no written history existed. Fagan also credits Sir Mortimer Wheeler, a renowned Old World archaeologist, for encouraging him to write for popular audiences. Fagan recalled Wheeler's advice in his 2004 retrospective: "Write about the past for the public. . . . We need a new voice who's worked outside Britain." Fagan's first textbook, *In the Beginning*, was published in 1972 and is still in press—in fact, it is now in its 11th edition. Since that time, he has edited the massive Oxford Companion to Archaeology and published over 30 books on topics including general world prehistory, the origins of modern humans, native North America, Mesoamerica, historical archaeology, archaeological methods, history of archaeology, and paleoclimatology, not to mention sailing.

A biography of Fagan would be remiss to neglect to mention his love of sailing. He is an accomplished sailor who has charted courses in Europe, the Mediterranean, the Caribbean, and California. Like archaeology, his devotion to sailing is reflected in the publication of no less than eight books on the subject and an editorship at *Sailing* magazine.

Along with popular archaeology and sailing, Fagan is equally committed to undergraduate teaching, which he sees as the key to the long-term viability of the discipline in an archaeological world marked by academic overspecialization and cultural resource management. To this end, he has pioneered new and alternative methods to teaching large undergraduate archaeology courses. His work in this area culminated in the cocreation of a multimedia approach to teaching Anthropology 101 called "Anthropology 3," which has since become one of Apple Computer's demonstration projects.

Whether in research, teaching, or popular nonfiction, it is safe to say that the world of archaeology

would not be the same without the prolific contributions of Brian Fagan.

FAMILY, EXTENDED

Extended families, more so than nuclear families, are characterized by great variation in type and form. The term *extended family* is usually applied to family systems where the ideal is for multiple generations to live together, so that a man and his wife live with the families of their married sons (or daughters in a matrilineal society) and all other unmarried children. This may be accomplished by adding rooms or ells to houses or by clustering huts or tents into a compound or in close proximity. When the married sons stay with their parents, it is known as a *patrilocal* residence pattern and when married daughters remain and the sons move to their wives' families' home, that is referred to as *matrilocal* residence.

Sometimes included as a type of extended family are *stem families*, which require one family member, usually the oldest son, to inherit all the family property while remaining responsible for unmarried sisters and underage brothers, and *joint families*, where property is held in common by all direct male descendants, who jointly benefit from the family property.

While the extended-family form is the ideal in many societies, it is rarely fully expressed. Wealthier and higher-status families are more likely to be able to attain the ideal because of greater resources, especially larger land holdings, which can use the labor of the family members. Another factor influencing the prevalence of extended-family households is the mortality rate;

Source: www.downtheroad.org, The Ongoing Global Bicycle Adventure.

sons frequently want to break away from the family compound and start their own household upon the death of the father. Last, the life cycle of the family combined with the ideal of the extended family suggests that many individuals in a society probably spent at least a small portion of their lives in an extended family, but that at any one time most families were not extended.

A major difference between nuclear and extended-family households is in the strength and direction of the emotional bonds formed within the family. In extended families, the emotional bond between the child and parent remains strong, and the bond between spouses may be comparatively weak or characterized by jealousy of the mother-in-law by the daughter-in-law. Daughters-in-law may spend much of their time with their mothers-in-law, more time than they spend with their husbands. Marriages are more likely to be arranged, with bride and groom not knowing each other before the wedding.

Another feature of interpersonal relations in extended-family households has to do with decision making and the handling of conflict. Decisions about many aspects of the family and household are made by an older individual, the head of the extended family. Men who are the fathers of their own nuclear family within the extended family but are not the head themselves are unlikely to exercise much decision-making power, even in areas such as child rearing and the education of their own children. Members of extended families typically rely on cultural norms of behavior

that allow them to avoid conflict, including an emphasis on the welfare of the group over the individual and techniques for neutralizing conflict in close quarters.

Extended families are more commonly found in medium-sized societies that are primarily agricultural. Extended-family households are able to marshal a large labor force to perform seasonal agricultural work, which makes them advantageous in agricultural societies. In large-scale societies with more social and spatial mobility, extended families

can be a hindrance to mobility and they tend to decline in frequency in more complex societies.

FAMILY, FORMS OF

Although efforts toward a cross-cultural definition of family are beset by difficulty and disagreement, in anthropological writings, different congregations of kin and affines (i.e., people related through marriage) have been labeled as specific forms of family, changing as new theories of kinship, marriage, or gender

have been developed. It has been shown that great social and cultural diversity and social change in family composition and structure can be found; much social and cultural anthropological research is dedicated to understanding this variation and changes over time. Multiple forms of family are, above all, differentiated regarding characteristics of family structure, composition, and residence pattern.

Forms Regarding Structure and Composition

In his influential work *Social Structure* (1949), George Peter Murdock defined the family as “a social group characterized by common residence, economic cooperation, and reproduction. It includes adults of both sexes, at least two of whom maintain a socially approved sexual relationship, and one or more children, own or adopted, of the sexually cohabiting adults.” The two-generation family composed of mother, mother’s husband, and their offspring was defined by Murdock as the *nuclear family*. This form is mostly found in hunting-and-gathering and industrial societies. On one hand, in times of hardship and catastrophes, little help is shown from outside, which means that in the case of the mother’s or the father’s death, the children’s lives become insecure. On the other hand, this form of family is well-adapted to a high-mobility life, be it the society of the Inuits or contemporary industrialized societies. This form of family is also common where there is a sexual division of labor. Murdock took this form of family as a universal human social grouping, but he also recognized that among the majority of world’s societies, “nuclear families are combined, like atoms in a molecule, into larger aggregates.” This composite family form is called the *extended family*.

The extended family, in the broad sense of the term, is a family, usually coresiding, consisting of more members than children and parents. An extended family may include grandparents, brothers, sisters, aunts, uncles, and so on. One important form of an extended family consists of two or more nuclear families affiliated through an extension of parent-child relationships, the nuclear family of a married adult joined to that of his and/or her parents (an extended family in the narrow sense of the term). An extended family need not to live in the same household. Kin provides the core relationship here. In times of crisis or hardship, families pooled resources among households, and kin moved between households,

extending the nuclear family to more complex forms. This is not restricted to non-Euro-American cultures or to the past. Research in Scotland and northern England in the 1980s, for example, suggested that the extended family was as important as the nuclear family in patterns of residence, household composition, and access to resources during periods of unemployment. Some researchers use the term *joint family* to refer to an extended family composed of nuclear families linked together by sibling ties. Much debate, moreover, has centered on the supposed breakdown of extended families with industrialization. But much of this debate rests on an oversimplified dichotomization of nuclear and extended forms of the family without defining what is meant by “extended-family ties” and which kinds of extended families are talked about. Murdock based his typology of extended families on the prevailing rule of residence. He distinguished the *patrilocal*, the *matrilocal*, the *bilocal*, and the *avunculocal extended family* (see the following variations in residence pattern). Extended families are often transitory and dissolving at the death of the parents, when inheritance makes it possible to divide family property.

Further forms of family regarding structural characteristics are found in cultures with multiple marriage partners, resulting in *polygamous families*. *Polyandrous families*, as one form of the polygamous family, consist of one wife/mother, her children, and two or more husbands/fathers. The polyandrous family is a one-woman/several-men family. The family generally starts with a monogamous mating pair. Later, a second adult male may join the family and assist in child rearing, although the men sometimes live in a separate house. The polyandrous family is found, for example, with ethnic Tibetans of Humla District in Tibet and in Nepal and with the Toda in India. The connections between polyandry and reproduction have long interested anthropologists, who have puzzled over the conditions in which a system of men sharing their wives with other men (thus sacrificing some of their own reproductive potential) might have developed. *Polygynous families*, the second form of the polygamous family, consist of a husband/father, two or more co-wives/mothers, and their children. The polygynous family is a one-man/several-women family. This form of family has puzzled male anthropologists to a lesser extent. Two thirds of the 849 societies examined by Murdock practiced polygyny. Today, polygyny and polygynous families are concentrated in Africa, the Middle East, India, Thailand, and Indonesia.

Source: Photodisc.

As traditionally defined, the nuclear family is based on the conjugal bond (i.e., the husband/wife bond), although some anthropologists distinguish between the nuclear and the *conjugal family*. But many societies place the primary emphasis on consanguine (blood) ties in structuring the family unit. A *consanguine family* consists of a mother and her children and her blood relatives (mothers, aunts, sisters, brothers). The central unit is not the conjugal bond, but blood. This kind of family is common where mothers do not have the resources to rear their children on their own and is found, for example, with the Nayars in South India. In this culture, the mother-children unit has no significant bonds to the father or mother's husband. This form of family is also called *matrifocal*, or mother-centered. The mother-centered family form is usually defined by the absence or relatively limited role of the father. Other frequently cited examples of matrifocal families are Black Caribbean families or families in Guyana.

For those stressing blood ties, the minimal definition of family is already satisfied by the mother-children unit. And some define the universal nuclear family group as that composed of a woman and her dependent children. In Euro-American society, the nuclear family (in the traditional sense) has been seen as the ideal. With this ideal in mind, for anthropologist Bronislaw Malinowski, a group consisting of a woman and her offspring was sociologically incomplete and illegitimate. And as mentioned above, Murdock also took it as a defining feature of a family that adults of both sexes are included. But this defining feature was not only challenged by single-parent

families but by same-sex-parent families as well. Even some quite early ethnographic accounts attested to the fact that the nuclear family in the sense of the heterosexual conjugal family was not as ubiquitous as the dominant theories maintained. There are situations in some societies (the West African Nuer and native North American among them) where women may take wives ("woman-to-woman" marriage), or men husbands. What is interesting in these situations is that

the people who are allowed to do this are often special, privileged members of society, such as female chieftains or businesswomen in West Africa, and shamans and priests in North America. Nevertheless, *same-sex conjugal* families, either gay or lesbian coparenting, are still regarded by most members of Western societies as "alternative" or "deviant" family forms. As far as lesbian coparenting families are concerned, new possibilities emerge. Until recently, only one of the women could be the biological mother. But reproductive technologies made it possible to think of biological motherhood in a dual way: The genetic mother and the birth mother could be different. One woman could contribute the genetic material, and her partner could become the gestational/birth mother. Advocates of the "traditional" heterosexual conjugal family fear the breakdown of the family due to these new possibilities, contemporary Western lifestyle, and women's increasing social autonomy in Euro-American societies.

Forms Regarding Residence Patterns

The issue of residence pattern is one of the most basic questions in ethnography. Because the location of the family unit has important logistical consequences, residence patterns have a long history of study. Traditionally, anthropologists have analyzed residence in relation to marriage. A *virilocal* (Latin, *vir*: man, husband) or *patrilocal* (Latin, *pater*: father) family is a family whose residence upon marriage is in the locality associated with the male partner's relatives or,

more specifically, with the male partner's father. For example, in the society of the Maya of Guatemala, a newly married woman goes to live with her husband in the household in which he grew up. An *uxorilocal* (Latin, *uxor*: wife) or *matrilocal* (Latin, *mater*: mother) family is a family whose residence upon marriage is the locality associated with the female partner's relatives or, more specifically, with the female partner's mother. This form is found mostly in horticultural societies and has been linked to the solidarity of the female working group. The Iroquois are an example, as women farm and own the harvest. In *ambilocal* or *bilocal* families, the family may choose either matrilocality or uxorilocal or patrilocal/virilocal residence. The family could live where the resources are best or where the labor is most needed. In *avunculocal* families, the family lives with the husband's mother's brother. This form of family is found only in societies where descent through women is deemed crucial for the transmission of important rights and property, as it is for the Trobriand Islanders, for example. A *neolocal* residence pattern means that a family establishes a new household in a location apart from either the husband's or the wife's relatives. This is the prevailing residence pattern of families in Euro-American societies.

Although these differentiations are very common, several alternative approaches to the analysis of family and residence have been proposed.

Additional forms of family are the *family of procreation*, also called the *family of marriage* and the *family of orientation*: the nuclear family a person establishes, consisting of his or her partner, sons, and daughters. Someone's family of orientation is the nuclear family into which that person was born and raised, consisting of his or her father, mother, brothers, and sisters.

In Euro-American societies, established ideas about the "natural" family in the public eye are being challenged because of the increasing number of single-parent families, same-sex unions, households based on friendship, and cross-cultural data, which stress different types of family and household structure. Anthropological research has shown the complexity of the family viewed in comparative perspective. The family will continue to be a major focus of anthropological research, although the understanding of family and forms of the family are currently being redefined.

FAMILY, NUCLEAR

The nuclear family is one type of conjugal, or marriage-based, family, consisting of a husband, wife, and their children who reside together. Characteristics of the nuclear family that set it apart from some other family types is that it contains only two generations and that it contains a married couple. A single-parent family is considered a nonconjugal family.

In large-scale, Western, industrial societies, nuclear and single-parent families are the predominant type of family form, but in other, smaller-scale, less Westernized cultures, the nuclear family may be relatively rare and unimportant, or even nonexistent. In larger-scale societies, individuals can function more independently of their families, and the functions that larger, extended families used to supply to their members have been increasingly taken over by other social institutions, such as schools, churches, hospitals, police, and paid leisure and entertainment industries.

Some historians and demographers have suggested that the rise of the nuclear family in northwest Europe, traced back to 1300 in some regions, developed in response to a unique set of ecological conditions, laying the foundations for industrialization hundreds of years before the first factories were built. Northwestern European families followed a neolocal residence pattern, whereby a couple did not marry until they were able to establish their own household.

In general, nuclear families are characterized by normatively stronger marital bonds between husbands and wives than are expected in extended-family or other societies. Societies where nuclear

Source: Ministry of Foreign Affairs–Photographic Service.

families are common are more likely to allow young people to select their own spouse, with less involvement on the part of their parents. Relations with in-laws are likewise attenuated, although kin-based work groups and socializing may still be extensive. Divorce is also more likely to be tolerated, with one spouse perhaps simply putting the other spouse's belongings outside their home to indicate the end of the marriage.

Nuclear families are less likely to be found in agricultural societies where most families work the land cooperatively. A nuclear-family structure facilitates mobility, whether it is migratory labor or movement to urban areas or across borders. The smallest societies, hunter-gatherers, are frequently organized into small groups of nuclear families who work cooperatively and are characterized by significant gender egalitarianism. Members of society are “produced” by families by the process of providing food, shelter, clothing, health care, and emotional intimacy. Individuals are also provided with social status

through membership in their families of origin, although in societies with many nuclear families, social mobility is typically possible, which allows individuals to have more of an influence over their own social class.

Nuclear families share with all families the function of producing new adult members of society through conception, birth, nurturing, and socialization. Families regulate the sexual activities of their members, allowing regular sexual relations between spouses and prohibiting sexual relations among all other members. When children in nuclear families reach adulthood, their legal responsibilities to their families of origin and their parents' obligations to them are generally reduced, replaced with voluntary companionship. This creates the possibility of extreme isolation for nuclear families, which have fewer resources for child care, elder care, and assistance throughout the life course.

FARBER, MARVIN (1901–1980)

The scholarly writings of 20th-century American philosopher Marvin Farber owed a great deal to the field of anthropology and the theory of evolution in both their scientific and conceptual ramifications. For him, humankind is a recent and fragile species on

planet Earth. From the cosmic perspective, he argued that our species has no meaning or purpose other than those value judgments that human beings themselves make in order to adapt, survive, and thrive in a material universe that is, for him, totally indifferent to the ephemeral existence of our zoological group.

Having been influenced by the thought of Ludwig Feuerbach, Karl Marx, and Ernst Haeckel, Farber's ideas are a contribution to philosophical anthropology. Thus, despite his early interest in phenomenology, Farber came to see it only as a method that had to be used within the perspective of a naturalist framework free from all dualistic, idealistic, and spiritualistic suppositions.

Farber was very aware of the predictive, explanatory, and exploratory powers of the theory of evolution. For him, humankind as societies of knowers and doers is a product of both organic history and sociocultural development. He held that all religious beliefs are grounded in those psychological wants, needs, and desires of our very vulnerable species. Furthermore, all human values must recognize the advances in the special sciences, the need for rigorous reflection, and a naturalist framework that embraces both a cosmic perspective and the implications of the empirical theory of organic evolution.

While stressing those perennial themes of inquiry in the history of serious thought, Farber spoke of the philosophical quest and saw as one of its major functions the critical evaluation and holistic synthesis of the natural and social sciences within a plurality of logical, cooperative, and complementary methodological procedures. He especially respected anthropology as an academic discipline, acknowledging that its facts, concepts, and approach are indispensable for any sound and valid view of humankind within nature.

There is a qualified optimism in his healthy-minded interpretation of the tenuous place of human existence within this material universe. Farber stressed that the natural world is independent of and prior to the human knower and the knower's sociocultural environment. Consequently, for Farber, the process of reflective thought occupies only an infinitesimal part of this dynamic cosmos, and it occurs only when there are sentient beings in action.

As an evolutionist, Farber warned about illicit transference: the unwarranted extension and application of an explanatory principle valid in a particular field of inquiry to other areas of investigation or realms of reality to which it cannot validly be

transferred and used. A glaring example of this fallacy would be the overextension of the descriptive mechanism of the *survival of the fittest* from biology to sociology, with devastating ethical results. For Farber, it must be remembered that in human inquiry each field of science has its own peculiar problems, research methods, explanatory mechanisms, and open-ended interpretations.

There is always a need to clarify the place of our own species within this material universe and to assess the status of mental activity in the context of organic history and sociocultural development. Farber followed the advancements in the special sciences and acknowledged that the ongoing findings in comparative primate behavior studies offer a striking confirmation of the scientific theory of organic evolution. For this naturalist and humanist as philosophical anthropologist, the goal of scientific philosophy is to increase human freedom, happiness, and longevity.

The Fayoum is a region located 60 km southwest of Cairo and contains archaeological remains from the past 12,000 years. Its most prominent feature is the Birket el-Qarun (Lake Moeris), the only freshwater lake in Egypt, covering an area of 215 km, whose

numerous crocodiles during Pharaonic times gave rise to the local crocodile cults for the crocodile god Sobek. The fortunes of the Fayoum settlements have always been closely linked with the lake water levels. Archaeological remains are focused on three primary periods of time: the Epipaleolithic and Neolithic time periods and the Greco-Roman period.

A number of archaeologists have worked in the Fayoum. Initially identified by the Napoleonic survey in the early 1800s, work was subsequently carried out by B. P. Grenfel, B. G. Hogarth, and A. S. Hunt in the late 1800s to locate papyri. G. Caton-Thompson identified the Fayoum “A” and “B” cultures in the 1920s, while F. Wendorf and his team explored the early occupants of the Fayoum and their connections to the Nile Valley in the 1980s and 1990s.

Early Periods of Occupation

Located in a large depression filled through glacial processes, the Fayoum was originally fed by a branch of the Nile, thus linking its rise and fall to the annual inundation levels. The earliest remains from occupations of the Fayoum date to 10,000 BC. Early inhabitants of the Fayoum (ca. 6500–5500 BC) combined fishing, hunting, and foraging, all made possible by the swamps and forests supported by the lake. This formed the basis for the Quarunian industry, known for flakes, blades, fishing, and large-mammal hunting, including gazelles, hartebeest, fish, and hippos. Grain grinding was practiced but not an integral part of the local diet. Nile fish caught in receding floodwaters facilitated fishing during the late spring each year.

Around 5500 BC, the people of the Fayoum were either replaced, displaced, or converted to the Neolithic culture, when they started farming wheat, grains, and barley, as well as domesticating sheep and cattle. The earliest evidence for an agricultural economy in Egypt can be found at the site of Mirimde Bene Salame, with cereals likely introduced to Egypt from southwest Asia, as well as domesticated sheep, goats, and some species of cattle.

Other possible origins include the northeast Jordan valley or Sudan or Saharan cultures such as those found in Bir Kiseiba or Nabta Playa. Even though the Fayoum people are culturally related to the Bir Kiseiba and Nabta people, resources locally available allowed them to hunt, fish, and gather for a much longer period of time. Numerous hearths

(ca. 5500–4500 BC) appeared along the lake edges, yet excavations have not uncovered permanent occupations, due to potential seasonal inhabitation in reed huts.

The Fayoum B and Fayoum A cultures occurred during this time, also known as the “Fayoum Neolithic” (ca. 5200–4000 BC). Numerous grain silos were observed at Kom K, with Kom W as the largest settlement from this period. Material culture observed includes pottery and concave-base arrowheads. Around 4000 BC, the Fayoum became a marginal area, due to human dependence on resources affected by seasonal changes in lakeshore levels. The Nile Valley became more reliable, with increased land to farm, and sites located along the Nile becoming trade and exchange routes.

Pharaonic Occupation

During Pharaonic times, Lake Moeris was known as *she-resy* and *mer-wer*, the southern lake and great lake, respectively. There is limited occupation in the Fayoum during the pre-Dynastic period (ca. 3700–3000 BC), with an intrusion of the Gerzean culture at the pre-Dynastic cemetery of Gerza and pottery similar to the pre-Dynastic settlement at Ma’adi. In the Old Kingdom, there is evidence for an Old Kingdom dolerite quarry road at Umm es-Sawan. The Middle Kingdom saw agricultural improvements in the area, with a major land reclamation project around 1970 BC. Temples appear at Medinet el-Fayoum and Kimim Fares as well as limited lakeshore settlements. The region became a resort area for the elite of Egypt in the New Kingdom, with colossi of Amenhotep III found at the site of Biahima. The lake levels are reflected in the times of high and low settlements: The lake levels are high in the Epipaleolithic, Neolithic, Middle Kingdom, and late New Kingdom, but are low in the Old Kingdom. There is an increase in settlements starting from the Late period, with Ptolemaic irrigation channels observed by Caton-Thompson in her work.

Greco-Roman Occupation

During the Greco-Roman era, hundreds of sites could be found in the Fayoum. These are known from both texts and archaeological remains. Most towns were founded during the reign of Ptolemy II, in a major land reclamation project surrounding the

Birket el-Qurun (Lake Moeris). Retired Roman military men and their families were settled in the Fayoum, which increased during the 1st and 2nd centuries AD. Many cults existed that were dedicated to the local crocodile god, with numerous temples. Most sites were abandoned by the 4th century AD, with some lasting through to the 7th century. Large sites founded by Ptolemy II include Dimai, or Soknopaiou Nesos (Island of Soknopaiou), along the northern edge of the Fayoum, with a temple complex, public buildings, houses, and four occupation layers, and Kom Darb Gerza (Philadelphia), along the eastern edge of the Fayoum, some 24 hectares in size. It existed as a major travel route between the Nile and Fayoum and a major administrative center. The most well-preserved town in the Fayoum is Kom Aushim (Karanis), located in the northeast, with many thousands of buildings found and inhabited to the 6th and 7th centuries AD. The Fayoum is most well-known for its Roman period mummy portraits (noted for their lifelike resemblances of the deceased), most recovered from the necropolis near present-day Rubayyat, north of the Hawara pyramid.

Current research being carried out by W. Wendrich and her international team of specialists in the Fayoum will help to answer questions surrounding human interactions with the environment and the location of new sites. The Fayoum has only grown more fragile with increasing urban development and, with numerous archaeological sites at risk, needs this work before the sites are lost forever.

FEASTS AND FESTIVALS

In the beginning of “the people,” the commensality and feasting had birthed a social mechanism, a central theme in our evolving society. Within cultures, the hearth symbolizes “welcome.” A feast is a celebration with foods, perhaps served only for the occasion, in unique and sacred containers. There may be gift giving either with or without a contractual obligation. Anthropomorphic, carved figures may be displayed either within the feasting area or outside, to welcome the guests. Name giving has been an important part of feasts by some cultures, like the tribes on the northwestern coast of the United States, carrying on the potlatch tradition.

As feasts evolved, rituals became attached, which signified the type of feast being held. Soon, these feasts became more complex, expanding into festivals involving specific etiquette, which molded community behavior. Feasts and festivals proliferated and assimilated cultures by blending rituals, as occurred with the early Christian and Roman observances, such as the creation of Christmas from the solstice celebrations. Could our very political system stem from the act of feasts and festivals? This is the question Michael Dietler and Brian Hayden pose in their analysis *Feasts: Archaeological and Ethnographic Perspectives on Food, Politics, and Power* (2001). How was surplus food used to start creating feasts and thus preserve the etiquette revolving around the display of finely crafted property appropriate to ensure survival of these mores?

Tlingit dancer Tootsie-a'-Kea-Tiny Barril performing an "entrance dance" at Tom Dalton's 2005 Tlingit Potlatch, Tulalip, Washington.

Source: Photograph by Pamela Rae Huteson.

What new feasts and festivals will be created in the future? As modern indigenous peoples are rediscovering their ancient pasts, will there once again be a revival of ancient rituals, perhaps returning to a moral universe, where Raven rules within his potlatch?

Feasts can be put into three categories:

- *Long-Term-Goal Feast:* There is a definite plan in this type of feast, such as to solidify alliances, to bring about peace, to settle disputes, or to raise the status of a chief's child.
- *Symbolic Feast:* There may be underlying goals in this feast, such as occur at a funeral feast to demonstrate future leadership. These feasts are usually sacred in character, such as memorial or marriage feasts, the first harvest, honoring the ancestors, births, adoptions, and rites of passage.

Tlingit Orator Chief Roy Williams III speaking before the first of three totems to be raised in Klawock 2003.

Source: Photograph by Pamela Rae Huteson.

- *Immediate-Goal Feast:* This is more of an impromptu feast and may not have any ritual foods connected with it. This may be a crisis or work feast, or perhaps when a judgment needs to be made or during the planning of potlatch.

Evolution of Feasting

Feasts are speculated to have originated prior to Paleolithic man. Hunting-and-gathering tribes were usually nomadic in nature and would call a feast with the advent of any sudden abundance of food. A case in point is the system of distribution among the Inupiat and Nootka Peoples. When a whale is taken, after a feast is held, the entire clan receives shares. The Inupiat call this the *nalukataq*, and in ancient times, this would last nearly a week and would signify the cessation of whaling. Nomadic peoples lacked the ability to store surplus food required for a large feast; consequently, these may have been started by seminomadic, transegalitarian tribes.

Gender reinforcement is visible in ancient feasts, as most often the females prepared and served the feasts, although historically, handicapped males would also take part in what was thought to be “women’s work.” The males did the hunting and developed their prowess and status as a result of their success and leadership positions. Some tribes observed a strict etiquette regarding certain foods; for example, the Koyukon distinguished between feasting on black and brown bear meat. The first feast was held by the hunters within the forest, to honor the bear’s spirit. The “best parts” of the meat were saved for the potlatch, and then cooked only by men. Adults have encouraged children to partake in feasting rituals in the past as Franz Boas (1858–1942), discovered among the Kwakiutl.

Various Rituals Observed

Beginning rituals would involve thanking the animal or Creator for bringing food to the clan. While doing

his study on Huna seagull egg gathering in 2003, Eugene S. Hunn was told to “have respect for everything” concerning the ritual of food gathering. Fasting may be observed in the beginning phases of a religious purification feast. A sacramental communal feast may be a totem feast, where the clan joins in eating the totem object (salmon or bear, for example) as the totem’s “power” is consumed, renewing the person’s individual connection with that power. Rituals have taken the form of dancing and singing, such as the Feast of the Dead, witnessed by Ernest Hawkes, in 1914, where the “Feast Giver” honored a departed loved one by dancing and wearing the clothes representing the gender of the departed relative.

Traditional oratory was important to the Tlingit People, as is set forth in the oral tradition recorded among the Tlingit by Nora and Richard Dauenhauer, in their traditional research entitled *Haa Tuwunóagu Yis: for Healing our Spirit* (1990). Because there was no written record, public speeches were given to reaffirm the owner’s rights to inherited privileges and

property. The Bella Coola, as other Northwest cultures, have utilized this time to bring honor to their given traditional family names and also to bestow revered names upon their children and those they adopt. Attendees witnessing these privileges are paid rich and elaborate gifts to remember the name, meaning, and history. Smoking has been part of some feasting rituals, as was observed by the Tlingits; they put tobacco in the fire while respectfully uttering the names of the deceased being honored, before smoking their native tobacco in their world-renowned and elaborately carved pipes.

Status reserved seating was observed in nonegalitarian societies, as was the displaying of valuables. The northwestern coast Natives observed a ritual of honoring the fish by returning the bones of the first catch to the water, to ensure future fish runs. With the Koyukon, honoring ceremonial animals took the form of a ritual, to return the bones of water creatures to the water and bones of land creatures to the land. These rituals were based on the belief; it was the choice of the

animals, fish, and fowl as to whether they wanted to be human food, depending on how they were honored.

There may be specialized structures built or made for feasting, such as the Inuit circular-stone seating arrangements, which stand out in their Arctic homeland and served not only as an area for feasts, but also for courts of judgments, as photographed by Norman Hallendy in 2000. In a dramatic ritual among the Inupiat at the Bering Strait, ceremonial items may be destroyed at the end of the festival, and at this time, masks may be thrown into the sacrificial flames. The Tlingits, Haidas, and Kwakiutl have been known to burn canoes, throw copper shields in the water (also known as “drowning the copper”), kill slaves, and tear blankets during their feasts.

Festivals

As rituals and customs evolved within feasts, festivals began to emerge. A festival usually accommodated more than one feast that observed set rituals. Alliances were often required from all of the kinsmen to prepare for a festival, with the lower caste doing most of the production and food gathering, including the exploitation of slaves. Seminomadic tribes or bands started developing festivals, such as the Inupiat with their “traditional trading fair,” held in the summer, where bands of Inupiat gathered to trade, visit, and feast.

The host, in observing said rituals (e.g., to honor the ancestors), may also serve to benefit that person or clan by raising their status to ensure a greater return, as in a competitive potlatch or the Inupiat’s “Great Feast of the Dead.” It would take years for both parties to gather wealth for distributing the gifts, at which the receivers assumed a contractual obligation to give as many, if not more, gifts in return at their feasting occasion. When the potlatch was banned in Canada in 1885, many hosts who gave away much wealth (e.g., rifles, pool tables, sewing machines, and so on) were never repaid, thus experiencing a great loss; but since the host takes on the “superior” status in outdoing his peers if he is not repaid, then at least that status remains.

Continuing Traditions

The act of feasting and of festivals is a long-standing tradition with humankind. The development of these occasions has brought about elaborate religious ceremonies, which are serious and formalized, as well as numerous light-hearted functions encompassing

Haida Carver Sáádúúts: Robert Peele, showing of a gift received at a potlatch, in a traditional manner.

agricultural or seasonal events, to name a few. As researchers and students alike reevaluate the feasts and festivals within cultures and how they have had an importance on the bonds created within the people of the study, this may bring a new depth in understanding ancient peoples. Modern cultures may continue to create new reasons for feasts and festivals, as well as resurrect and evolve ancient ones, as the north-western indigenous First People continue to do with the potlatch.

Bon Appetit!
The Feast is here to stay.

Feminism has been defined as a belief that women have been treated unfairly in society and that the situation should be rectified. This definition encompasses the two major aspects of feminism: It is a body of social theory that seeks to explain the universality of women's subordinate status, and it is a social movement acting in the interests of women through political action and other attempts to improve the lot of women. Feminism has profoundly affected virtually all academic disciplines as they have had to respond to criticism of their theoretical paradigms that ignored the effects of gender. Feminist thought has affected the humanities, the natural sciences, and the social sciences. In addition, feminism has affected all societal institutions, including the economy, the family, education, religion, and politics. It would be fair to say that feminism and the women's movement have altered the landscape of American life as deeply as any paradigm shift of the 20th century.

History

Feminism traces its roots to the Enlightenment, when thinkers such as Lady Mary Wortley Montagu and the Marquis de Condorcet championed women's education. Mary Wollstonecraft's *A Vindication of the Rights of Women*, published in 1792, may be the earliest feminist writing of the modern age.

The first wave of feminism and the women's movement began in the early 19th century among abolitionists, especially women abolitionists, who began to draw comparisons between the oppression of the slaves and the position of women in society; neither could own property in their own name, vote, sit on a jury, or testify in a court of law. In 1848 the first women's rights convention was held at Seneca Falls, New York, organized by Elizabeth Cady Stanton and Lucretia Mott. The suffrage movement won victory finally with the passage of the 19th Amendment, which in 1920 granted women the right to vote. After this achievement, the first wave of feminist activism died down for about 50 years, as many women and men assumed that with the vote, equality was assured.

The second wave of the feminist movement had its first stirrings during World War II, when women took on factory and other war-related work for the men who had gone overseas. Women also played a significant role in the military for the first time. Day care was provided for the children of working mothers, who were told they could accomplish anything. After the end of the war, the propaganda reversed; women were sent home to their children, who they were told now needed them at home, and consequently some women felt let down and deceived. Betty Friedan's book *The Feminine Mystique*, published in 1963, described what many women were feeling, a sense of malaise and purposelessness that led to feelings of despair and deep unhappiness.

Two prongs of feminism were important from the start: During the 1970s, organizations such as the National Organization for Women worked for legislation guaranteeing women equal opportunity in the workforce and equal rights under the law. Discrimination on the basis of gender became illegal, and the Equal Employment Opportunity Commission and other enforcement agencies backed up the laws. At the same time, women were making enormous strides in academia and altering the way gender was treated in research and scholarly endeavor. Out of this intellectual ferment, with cross-pollination from the world of social activism, various strains of feminist theory emerged.

Theoretical Perspectives

Radical feminists take patriarchy as the starting point of women's unequal treatment. They argue that patriarchy is separate from and predates capitalism. Men

as a group dominate women as a group, with men being the primary beneficiaries of women's subordination. Patriarchy is related to male violence against women. Many radical feminists consider rape the ultimate expression of male power and believe that male appropriation of female bodies through violence includes marriage and childbearing as well as domestic labor.

Unlike radical feminists, *Marxist feminists* consider gender inequality to derive from capitalism, not patriarchy. Men's domination of women is a by-product of capital's domination over labor. Capital depends on women's domestic labor in the home to provide for the day-to-day care of workers and the care and socialization of the next generation of workers.

Liberal feminists interpret women's subordination as a summation of numerous small-scale deprivations. Their view is grounded in the classical liberal position that individuals should be free to develop and pursue their own interests. Liberal feminists accept the basic organization of society, including capitalism and democracy, but seek to expand rights and opportunities for women.

Difference feminism refers to the ideas of feminists who believe there are significant inborn differences between men and women and who argue that society should adopt more feminine values of pacifism and nurturance.

Eco-feminism draws parallels between male domination of women and human domination of the earth and promotes close connections between feminists and environmentalists.

Contribution of Feminism

Feminists have brought many issues to the attention of scholars and researchers. The first of these is simply the importance of taking gender into account in research. No longer is it acceptable to conduct research only on male subjects or to talk only to the men in a household or village. Secondly, a gendered perspective encourages researchers to see the world from the viewpoint of the oppressed and the other. Social life is understood to consist of multiple power relations in which different groups stand in different relations to one another based on group membership and identity. Gender studies show that the world is seen in terms of contrasting pairs of attributes, one pair being male and female. Patriarchy is a model for the way the colonial powers exploited subject peoples or the way humans exploit the earth.

Within anthropology, feminism has had fundamental effects. For example, physical anthropologists challenged the dominant *man-the-hunter* model, which posited analogies between male-dominant African savanna baboons and the evolution of male-dominant human societies. Noting that primates more closely related to humans, such as chimpanzees and bonobos, are less male dominant and can be described as egalitarian or even female centered, feminists have proposed the *woman-the-gatherer* model, which has had far-reaching influence. Research now focuses on the importance of food sharing in the evolution of humans and human culture.

Current issues in feminist anthropology include questions about the extent to which anthropologists can reinterpret older ethnographic works to look for hidden or unacknowledged sources of female power, by, for example, retheorizing kinship relations. The issue of politically motivated research and the role of the anthropologist in advocating for dispossessed and marginalized people continues to be controversial both within the field and between anthropologists and the wider community.

Biologically, fertility is the ability to reproduce and bear children. The term also refers to the fertility of land, animals, and plants. Culturally, the concept of fertility is conceptualized and articulated in various ways. Fertility has been the subject of both anthropological and historical studies.

Anthropologists, archaeologists, and ethnologists have long been interested in the fertility of preindustrial societies. Methodologically, such studies have often been conducted as distinct from demographical and reproductive biology studies.

Anthropologically, studies have produced conflicting results on the relationship between agriculture and fertility. A study by Sellen and Mace used various statistical methods to establish whether there is a relationship between the level of fertility in human populations and the form of economic subsistence within a society. Such a study goes beyond the nature-culture dichotomy, and results point to an increase in fertility in agricultural societies. However, they admit that the mechanisms for this remain unknown.

One problem with studying fertility anthropologically is that of ethnographic time. An anthropologist will need to spend a long time with a given population if he or she wants to obtain a picture of biological fertility, its nature, and implications.

How fertility is conceptualized is tied to the nature/culture debate. If nature and culture are considered dichotomous, fertility will be interpreted in terms of ecological determinism. On the other hand, the postmodern critique of the nature-culture dichotomy has made it clear that such a dichotomy is fallacious. Combined with the recognition that even sex is a cultural construction, fertility cannot be considered simply in terms of nature.

Archaeologists have traditionally placed a strong emphasis on fertility, usually vis-à-vis Neolithic culture. While Paleolithic people possessed many of the cultural capabilities of modern humans, they have been explained mostly through an ecological framework. At most, fertility is applied to “fat” figurines.

However, the Neolithic is often interpreted within a social rather than an ecological framework. One of the assumptions that has characterized Neolithic studies is that people were dependent on agriculture and thus needed a belief system to protect, strengthen, and promulgate fertility.

The concept has been widely applied to the interpretation of various female and seemingly female Neolithic figurines. This, in turn, is tied to a wider set of assumptions encompassing birth, sexual union, nurturing, and the cycle of growth. These attributes are mostly associated with motherhood, which, being one of the universal human realities, has often been conceptualized in terms of growth and nurturing.

While the universality of motherhood is undeniable, it is fairly simplistic to think in circular terms involving women, fertility, agriculture, and procreation. While the Neolithic reached various parts of the world, this phenomenon was by no means homogenous. There is no reason to assume, therefore, that the gradual spread of agriculture led to a universal, homogenized belief system with fertility at its core.

The evidence touted for celebrations of fertility, goddesses, and female-led rituals is open to various interpretations. The Neolithic body of statuary is immensely varied, and, while there are representations of pregnancy and birth, there are also many representations that are not. This does not mean that as a concept, fertility was not important in past societies. The consciousness that women carried unborn children and gave birth was an essential part of humanity’s development. The fertility of animals would have been known to hunters, and when agriculture gained prominence, observation would have yielded information on the fertility of both land and domesticated animals.

Feuding is a series of revenge-based killings that not only result in the loss of human life but also contribute to the disruption of the social order. There are five essential elements to feuding: (1) Kinship groups are involved; (2) homicides take place; (3) the killings occur as revenge for a perceived injustice or affront to honor; (4) three or more alternating killings or acts of violence occur; and (5) the violent encounters take place within a political community. Nearly half the societies studied by anthropologists have had feuds occur within them. Feuds can be divided into two types: feuding without compensation, in which there is no institutionalized means by which compensation can be paid, and feuding with compensation, in which payment of compensation can prevent a counterkilling, thereby stopping a feud. Cross-cultural studies suggest that the second type of feud outnumbers the first type about 2 to 1. Theories of feuding tend to focus on only one of these two types.

Dividing the world's societies into those with and those without feuding permits the identification of two types: (1) societies with fraternal interest groups, which have much conflict, including feuding, internal war, rape, and intrakinship group executions, and (2) societies without fraternal interest groups, which have little conflict, no feuding, no internal war, no rape, and polity-wide executions. Fraternal interest groups are localized groups of related males who defend the interests of their members. These groups come into existence through the practice of patrilocal or virilocal residence. Polygyny can also produce fraternal interest groups. Otterbein and Otterbein showed that when patrilocal residence and polygyny were combined, the likelihood of feuding greatly increased. Divale and Harris later showed that such societies had a "male-supremacist complex." Mistreatment of women and female infanticide accompanied the complex.

Type 1 societies can be divided further, based upon whether councils of elders are present. While all political communities have a leader, some have councils, and some do not. If a polity with a council is at war, the leader may be able to prevent feuding. A leader with the backing of a council may also be able to insist that a kinship group carry out the execution of a wrongdoer in its rank. All the theories listed below

except for world systems theory are predicated upon the assumption that fraternal interest groups are present and generating feuds.

Theories of feuding that appear to pertain to societies without compensation include those theories that refer to feuding as self-help, folk justice, or quasi-law. A revenge killing is viewed as a "counteraction" which leads to a "correction." Another approach known as "world systems theory" argues that commercial expansion leads to disruptive social change, which leads to out-of-control violence. World systems theory has also claimed that such expansion has created warfare in regions where it had not previously existed, "war in the tribal zone." A third theory views blood revenge as not only defining groups, but preserving them. Retaliation, based on deterrence theory, is believed to prevent counteraggression. Empirically, this does not occur, but if it leads to the elimination of one group, the survivor group has achieved the desired results.

Other theories of feuding appear to pertain only to societies with compensation. In societies with patrilineages organized into segmentary lineage systems, Max Gluckman has identified "peace in the feud." Lineages make peace through the payment of compensation, thus uniting to form larger kinship groups that feud with each other. Another theory, argued by Christopher Boehm, views the payment of compensation as a means of controlling conflict: Feudists realize that uncontrolled armed combat within the polity would lead to huge casualties.

FEUERBACH, LUDWIG (1804–1872)

German philosopher Ludwig Andreas Feuerbach is noted for his materialistic philosophy of human existence. Born in Bavaria, Feuerbach was raised as a Lutheran in a traditional Catholic state. Influenced by devout and resolved parents, Feuerbach's scholastic terms at the gymnasium in Ansbach provided the basis for exploring his interests in scripture and pious attitude, which directed him toward the area of theology. However, his theological orientation became severely compromised prior to his entrance into the University of Heidelberg. Although the reasons for his shift in attitude concerning theology are a point of speculation, his study in theology was subverted by his growing interests in philosophy. Considered a "left Hegelian," it was the philosophy of G. W. F. Hegel (1770–1831) that was particularly damaging, ultimately causing fissures in his view of the relationship between theology and philosophy. Unable to complete his education due to financial reasons, Feuerbach attended the University of Erlangen, whereby he received his doctorate in philosophy.

Feuerbach's academic career was less than illustrious. He was a teacher of philosophy at the University of Erlangen for a period of 6 years (1829–1835). Due to his highly critical positions on both philosophy and theology, his controversial views had left him unemployed. This fact had kept his academic and professional contributions to a minimum; yet his influence was great. Views in *Thoughts on Death and Immortality* (1830), *The Essence of Christianity* (1841), and *Principles of the Philosophy of the Future* (1843) had influenced great thinkers such as Nietzsche, Freud, and, most notably, Marx. Though his intellectual circle was a source of sociopolitical problems, his marriage to Berta Low in 1837 could be considered a joyous juncture. However, the move to Bruckberg with his new bride would end up being

futile. The family business gained through marriage became bankrupt and forced the couple to move near Nuremberg. With failing health and near destitute conditions, Feuerbach continued to be an advocate for philosophical and social change (for example, Marxism and the women's movement). Though his activism is not well-known, his noteworthy contributions were in his ability to articulate the eventual implications of evolution within a materialistic and naturalistic framework. Essentially, Feuerbach stated what Charles Darwin (1809–1882) did not articulate: the beginning of the end for theology.

Concepts of materialism and the process view of change are not new in the history of thought. The philosophies set forth by the pre-Socratics evaluated our species completely within both a materialistic and naturalistic framework. Explanations concerning the origin of our species and the processes of change were explored by philosophies of Anaximander, Heraclitus, and Parmenides. Though these ancient Greek philosophers did not have the evidence or the benefit of modern science, their acute observations and rational speculation removed the shroud of myth and superstition, ultimately serving as a beacon to which future materialistic philosophies could relate. In this same manner, Feuerbach had seen the apparent contradictions within theology and philosophy. Without the beneficial evidence of evolutionary theory provided by Charles Darwin, Feuerbach evaluated our species in a completely materialistic framework. As Feuerbach stated, the implications for theology were evident: the total dissolution of theology into anthropology. Such a task would require introspection in the deepest parts of the human psyche. The resulting answer would require an understanding of the human condition and strength in viewing human mortality.

Unlike the articles of faith and traditional theology of Christianity, concepts of the soul, God, and immortality have skewed our species's own ontological and teleological reality. According to Feuerbach, human beings, necessitated by physiology, possess the capabilities to distinguish themselves from the rest of nature. This act of distinguishing serves as a means to understand the relationship among our conscious being, nature, and the perceived essence or soul. Yet the essence or soul is indistinguishable from nature. When rationality seeks to distinguish the parts of this relationship, the outcome is an expressed desire for immortality and an explanation for a natural

phenomenon. This act becomes ritualistic, essentially creating a creative spiritual being. However, as Feuerbach points out, this desire for causal explanation results in the projection of our own humanity that is beyond the spatiotemporal plane of existence.

In Feuerbach's evaluation, the relationships depicted in the theological concept of the Trinity encompass the psychological unity of the individual in relation to himself and the community. As Feuerbach stated, God the Father is equated with understanding (intelligence); God the Son is love (warmth). This combination of love and understanding is the mind of the total individual. The Holy Spirit is the expression of love between God the Father and God the Son, the bases of religious emotive desires and an objectified religion. The God the Father and God the Son, through the Holy Spirit, becomes a unity that creates a community. The Virgin Mary, however, allows for the actualization of this love and community, for love is a divine feminine principle that already exists in God the Son. The Holy Virgin becomes a necessitated and integral part for the actualization of this Trinity. Through the Immaculate Conception, God the Son becomes a paradoxical being; a negation of God the Father and affirmation of humanity. This concept of the duality of Christ (Christology) allows for the visibility of God the Father within the spatiotemporal plane of existence. The existence of God the Son, through his death and resurrection, gave the faith and hope for the very immortality that our species continuously sought. It has become consciousness trying to circumvent the inevitable, that being a complete and absolute death.

Being aware of our own mortality is a direct consequence of possessing a greater degree of consciousness. The quest for immortality begins with this consciousness yearning for both contemplation (an object) and love. Together, these needs become an identity by which an individual can interact within a community. However, as Feuerbach stated, the implications stemming from a projected God become evident; death is final and complete. Death is the total dissolution of your existence within space and time, a negation of the spirit, reason, and consciousness. In this manner, reason, spirit, and consciousness cannot transcend death or exist beyond this spatiotemporal existence. Personhood, derived from our humanity, is the essence of being human in this life and only in this life. Only in this contingent human life can an individual be considered immortal. At death, being a fulfillment

of the precondition of existence, the unity of matter, consciousness, spirit, and reason cease to exist. The ultimate surrender to death becomes an act of love derived from freedom.

Feuerbach's philosophy may be seen as nihilistic; yet his perspective has more liberating and probative value. Without the evidence provided by modern science, Feuerbach exposed the contradictions within theology and modern philosophy. Dismissing biblical narratives, theological and philosophical rhetoric, Feuerbach placed our species back within a materialistic and naturalistic framework. Viewing the history of our species, the reconstruction of theistic explanations could be reduced to human psychological projections of our own humanity. This projection is necessitated by the natural processes stemming from our materialistically based consciousness. Relating to these anthropomorphic entities allows our species a sense of control over the uncontrollable or the inevitable end of existence. These facts do not deter from the quality of human existence; rather, they should be a source of strength and liberation. No longer should our species be a slave to its own projected multiplicity found in God. Our species should reclaim what it has freely given, our total humanity. Essentially, God is humankind's own ideal ontological and teleological perspective in the process of actualization. This process should be reflected in a new philosophy.

Feuerbach's claim that the task of the modern era was the realization and humanization of God would essentially negate over 2,000 years of philosophy and theology. Although empiricism began this transformation, modern philosophy had taken theological concepts into philosophy (for example, Descartes). Feuerbach had seen the need for another transformation, essentially a new philosophy as an outgrowth of the old. In the new philosophy, Feuerbach sees existence as love, and it is this love that will be the basis of the new philosophy. It will be the essence of feeling within consciousness that transforms the heart into mind. Love is the criteria of all being and reality, all of which should be turned into action. Necessitated by previous philosophical thought, Feuerbach states that the new philosophy had taken theology and dissolved theistic reason and heart into the very subject of anthropology. Thus, anthropology, combined with physiology, is seen as the universal science, beyond the revealing essences of humanity expressed in art, religion, and philosophy. It will be the understanding

of the human predicament that will change love into human action. Conscious of our precarious material existence, Feuerbach's hope is that in the process of reclaiming our humanity, the basis of existence, love, will express itself among all members within our community. This new philosophy was probably the basis of Feuerbach's view on social change and equality. Ultimately, this new philosophy would act to continuously redefine our own ontological and teleological existence within a dynamic and evolving universe.

FIELD METHODS

The various ways anthropologists conduct research in naturalistic settings, or in the field, are called field methods. They include participation in social life and various forms of observation. Anthropology relies on field methods as its ultimate source of information. Research in the field, known as fieldwork, involves collecting primary data on humans, other primates, and the objects and processes relevant to their lives. Through further examination, analysis, and comparison in library, laboratory, or office settings, researchers produce the discipline's general principles and theoretical advances.

Various field methods are used, depending on the data available, to illuminate a chosen problem. The diverse range of interests in anthropology is usually represented in the North American tradition by reference to its four subfields, namely, physical or biological anthropology; archaeology; sociocultural anthropology, also known as cultural or social anthropology or ethnology; and linguistic anthropology. There is, however, significant overlap in the kinds of data, and therefore the field methods, used in each of the subfields.

Methods of the Four Subfields

Biological Anthropology

Physical or biological anthropology makes use of field methods combined with laboratory work to understand aspects of humankind as a biological species. The place of humans in nature, their anatomy, physiology, evolution, similarities and differences with related species, physical adaptations to various environments, and biological diversity are all topics of interest to biological anthropology and are studied in the field.

Biological studies of deceased individuals and past groups make use of archaeological techniques to acquire fossil, bone, and other tissue samples and record the context in which they are found. Genetic and medical studies use blood, other physical samples, and anthropometric data, such as weight and height, collected from living or deceased individuals. Ethological or animal behavior studies of nonhuman primates make use of social observation and limited participation in animal groups.

Archaeology

Archaeological anthropology uses field methods to understand all aspects of the human past, with particular emphasis on what can be learned from remaining material culture, including artifacts and stratigraphic contexts. Field archaeologists conduct landscape surveys and sampling to locate sites of past human activity and identify patterns of occupation of the landscape. They conduct controlled excavations to collect artifacts and human remains, from which they assemble detailed data about particular sites.

In ethnoarchaeology, living people are observed and joined by means of participant-observation and conversation in order to learn how artifacts are made and disposed. Discarded objects and the processes involved in the formation of archaeological sites, or *taphonomy*, are also observed to learn how to interpret the archaeological record.

Sociocultural Anthropology

Sociocultural anthropology studies contemporary human groups in the field in order to understand the range of social relationships and organizations that human groups exhibit, as well as the learned beliefs and values that guide behavior. Most fieldwork in this subfield is directed toward producing ethnographies,

or written descriptions of ethnic groups. Thus, ethnological field techniques are often termed *ethnographic methods*.

Living among the people under study, ethnographers use observation and description of the settings in which people live, participant-observation in social activities, various forms of interviewing, and focus groups. Participant-observation is cultural anthropology's central contribution to the methodology of social science.

Linguistic Anthropology

Linguistic anthropology is concerned with language and its relationship to human culture and biology. The field methods of linguistic anthropology include interviewing speakers of a language; engaging in participant-observation to discover locally important social contexts and corresponding language use; recording naturalistic utterances and discourse; and describing nonspoken forms of language, such as writing systems in physical media and visual signing.

Linguistic anthropologists in the field need to learn local languages in a naturalistic setting, without the aid of written texts or trained teachers. Language structure, including phonology (sound systems), morphology (word structure), and syntax (sentence structure), can be worked out in the field by collecting numerous texts for comparison and analysis. The ways in which language use intersects with social and cultural conventions, including the linguistic forms used in particular situations and the cultural meanings attributed to them, are best studied in the field.

Categories of Anthropological Field Methods

All anthropological field methods can be grouped into five basic categories: (1) material observation, (2) biological observation, (3) behavioral observation, (4) direct communication, and (5) participant-observation. All five types of field methods involve observation, including the use of any of the five human senses to acquire information about the environment.

There are two basic means by which the field researcher engages with a topic of study: *subject-object* and *subject-subject relationships*. A subject-object relationship is pure observation, involving a subject (the observing anthropologist) and an object (the observed thing, setting, or person). Subject-object relations are one-way, in that an active observer collects information about a passive, independent, or nonresponding

object. This is an appropriate method to learn about inanimate objects, including artifacts, which reflect human and nonhuman primate activity. It is also ideal when collecting data on what people actually do as opposed to what they say they do or when biology and behavior are being observed without purposeful input from the people under study.

Subject-subject relations, on the other hand, involve a mutual, dialogical relationship between two thinking beings. This relationship is ideal for research situations in which the people studied are capable of and willing to communicate information about their inner states or beliefs. The subject-subject mode of engagement allows the meanings, abstractions, and mental models of informants to be directly communicated. These data are among the most interesting and rich forms of anthropological knowledge. While all field methods involve observation, they vary in the degree to which subject-object or subject-subject engagement is used.

Material Observation

The observation of physical settings provides the best information on the material foundations of social life, including ecological and economic relations. Observation of physical settings is also the most reliable method for producing evidence of actual, as opposed to ideal, behaviors, which may be repressed or denied by the populations engaging in them. Family, social organization, and even ideologies respond to environmental conditions and leave physical traces.

Observing objects and settings allows the description and analysis of a range of physical characteristics. Anthropologists in the field document landscapes, natural objects, built environments, architectural features, and artifacts.

Contemporarily occupied settings are visible and in use and are often easily accessed, although gaining access may require negotiation with local people. Material remains of past behaviors, though, are often buried and deteriorated, making their discovery, recovery, and analysis challenging in other ways. Because material remains are often the only available evidence of past behaviors, archaeologists are most consistently developed and specialized in the study of material culture in the field.

Archaeological methods for recovering objects and settings are designed to allow the maximum amount of information to be obtained, preserved, and communicated. Survey methods vary depending

on the size and characteristics of the terrain to be mapped for sites of interest, and these methods often make use of statistical techniques to ensure representative coverage. While survey techniques need have no impact on the material record, excavation systematically destroys contextual information about where objects were found in relation to one another. Therefore, excavation is done using an exactly surveyed, three-dimensional grid system, and each layer of soil is slowly and painstakingly removed and a careful record made of each stratum and how any objects found were situated.

Observing materials provides a window through time because of the relative stability of some material traces of behaviors. These methods produce data from objects rather than people, but in combination with the other methods of anthropology, they provide insight into how people make, use, and understand materials.

Biological Observation

Humans and related primates are biological species that can be studied in the field either as individual organisms or as populations. Such study can use methods that train observation on the form, function, and evolution of life. This group of methods includes gathering data on the anatomy and physiology of humans, hominid ancestors, and other primates.

Some of these data are recorded in the field from living subjects, using calipers, tape measures, scales, and other devices. *Anthropometry*, as this biological measurement is called, can be done either in the field or in the laboratory and provides data on such variables as stature, growth rate, and nutritional status of populations. In addition, samples of bodily fluids can be taken in the field and tested in the laboratory for blood group, diseases, and genetic characteristics and affinities. Biological observations can also be made of nonprimate species in order to determine which animals and plants are present in the environment and the ecological relations between these and the population being studied.

Refined physical observations are made in the laboratory, but contextual information, such as the disposition of the remains in relation to one another and surrounding objects, are discovered in the field and form the basis for sophisticated interpretations. Thus, field methods for collection and documentation of physical remains specify the same careful and detailed

care that artifacts in archaeological sites require. Tiny biological samples, such as bone fragments and burned grains, can be retrieved by shaking soil through screens and by flotation, in which soil is placed in water, which allows light carbonized materials to float to the surface, where they can be removed for identification and study.

Biological observations are also made of fossilized remains of human ancestors and other species, and in these cases the field methods of paleontology come into play. Fossils are often embedded in sedimentary rock and are discovered through systematic survey of landscapes where sediments of appropriate age are eroding on the surface. Once an appropriate area is identified, excavation can reveal more materials and can provide geological samples of plant and animal remains, which can be tested in laboratories to determine the approximate age of the fossils as well as climatic, floral, and faunal information about the time when the fossilized animals lived.

Biological and material observation overlap when artifacts and human remains are found in association. For this reason the two groups of methods are often combined. For example, skeletal material associated with grave goods reveals information about mortuary practices and social status.

Physical anthropology traditionally emphasizes the observation of anatomy rather than physiology, which is left more to medical study. However, one extension of physiology, behavior, is of central interest to anthropology and is, for the most part, best observed in the field.

Behavioral Observation

All primates exhibit behaviors, defined as volitional movements, that can be observed directly in the field. These behaviors include kinesics, dance, and speech, as well as specific intentional movements such as ritual performances and food procurement. Behavior, in other words, refers to actions that derive at least in part from intentional direction. These actions include gross movements such as walking or speaking, but not physiological measures like heart rate, although some physiological measures are influenced by volitional behaviors.

By observing behaviors without engaging with the observed individuals, anthropologists can document interactions without influencing them. The primatologist, for example, can watch a monkey troop from a distance using binoculars. Such methods are also

useful in situations in which linguistic communication is not possible, such as the earliest phase of some cultural anthropology fieldwork.

Many nuances of daily life reveal themselves to the quiet and patient observer of behavior. Through these observations one can develop a typology of the kinds of behaviors that are repeated and keep a record of how often and in what circumstances individuals undertake them. For example, one can describe grooming, greeting, and ritualized actions in a relatively objective manner by employing pure observation. Initial language learning also benefits from simple observation of utterances. Certain sounds and words are often repeated, allowing an initial entry into an unfamiliar linguistic world.

When linguistic communication is possible, one can listen to others' utterances without engaging in conversations. Here, the behaviors observed are linguistic and thus include information on meanings and inner states, but such communications are not truly dialogic, as direct communication is.

Direct Communication

This group of field methods includes all means of linguistic, paralinguistic, and other conscious interaction between anthropologist and research subjects. Rather than merely observing a living person or animal or taking notes on an inert object, these methods include two-way communication and allow the deepest possible exchange of information on mental states between two minds. In other words, direct communication is a subject-subject rather than a subject-object means of encounter.

The weakest form of direct communication is the survey, comprised of a series of standard questions, often requiring numerical or precisely formatted answers, distributed to a large number of people. Surveys are particularly useful for providing information, summarizable in charts and graphs, about whole populations. To ensure that survey results are representative of very large groups, for which complete coverage is impractical, the surveys must be distributed to a representative sample of the population.

Surveys are favored in sociological research but are used only lightly in anthropology because of their tendency to distance the researcher from the subjects and because they can be awkward to use among illiterate populations. Surveys can be conducted in some situations by mail, that is, without the anthropologist's having to enter the field. However, anthropologists

can also administer them in person in either written or oral form or distribute them directly while in the field.

Among the most valued field methods in anthropology are interviews, which are conversations between the anthropologist and informants and are designed to elicit a specified kind of information. In formal or structured interviews, the anthropologist provides a standardized list of questions. These are carefully planned to provide data capable of addressing theoretical and empirical concerns. Formal interviewing is a particularly useful method for producing comparable, quantifiable data on a particular topic. Its disadvantage is that it can force informants' knowledge into predetermined categories, ratifying rather than enriching and correcting theoretical models. Furthermore, as an artificial form of communication, it has the potential to stifle the more natural and genuine exchange of ideas that is found in informal conversation.

In informal or unstructured interviews, anthropologist and informant chat about a set topic. While the anthropologist has particular questions and a range of issues in mind, he or she allows the conversation partner to indulge in digressions and tangents and to take a great deal of control over the content of the discussion. The data produced by informal interviews are relatively idiosyncratic and thus often not amenable to statistical analysis. However, they may represent the best compromise between obtaining data to test a particular hypothesis and gaining insight into local views.

In focus groups, the researcher brings together several people selected for their particular knowledge or social roles and moderates a discussion among them about a topic of interest. The advantage of focus groups is that the participants jog one another's memories, encourage one another, and together can provide a more complete, nuanced, and publicly acceptable account of the topic of interest than an individual interviewee could.

The simplest yet also the most intimate and rich form of direct communication is a spontaneous conversation between the anthropologist and an informant. Interlocutors are most likely to speak in an unselfconscious manner, revealing those things that are most important to them.

Finally, there are forms of direct communication that are nonlinguistic but nevertheless often deeply revealing. First of all, during conversations and interviews, a great deal of valuable information is conveyed

paralinguistically, by such means as tone of voice, facial expression, and gesture; although these paralinguistic modes could also be categorized as observed behaviors, in a conversational context they are often used to enrich direct communication.

When the interaction is between a human researcher and a nonhuman primate, nonlinguistic behaviors are a valuable medium for direct communication. Calls, gestures, and glances can communicate feelings and desires between species. In ethnological field research, however, anthropologists must avoid assuming that expressions resembling ones from their species and culture have a similar meaning for another species. Nevertheless, anthropological researchers of nonhuman primates can attain a remarkable degree of direct communication with their research subjects without the benefit of language or mental apparatus identical to the other species.

Direct communication allows intentional transmission between researchers and subjects of information about internal states. However, except insofar as the local language and its idioms are used, researchers using direct communication need not enter the world of their informants behaviorally. Crossing that threshold characterizes the final group of anthropological field methods.

Participant-Observation

Participant-observation involves the immersion of the researcher in another social world. The researcher seeks to emulate the subjects' behaviors and thought patterns in order to achieve an empathetic understanding of their points of view.

The attempt to emulate local ways of life gives the researcher a firsthand experience of what they are like, and it demonstrates the researcher's respect for local customs, which may improve rapport. However, it must be stressed that even though an anthropologist lives in a local style of dwelling, eats traditional foods, attends native rituals, and so on, the anthropologist does not have exactly the same quality of experience as these activities evoke in local people. This is so first of all because the anthropologist does not merely participate in routines but is highly conscious and observant, taking nothing for granted and noting the experience in great detail. Second, if the anthropologist hails from another cultural background, these new experiences will be registered in the context of earlier experiences that are different

from those of local people and that may on a personal level seem strange or even immoral.

Participant-observation is suited almost exclusively to the study of living human societies. To an even greater degree than interviewing, it allows the anthropologist to attain a sense of local points of view, cultural assumptions, and social conventions because one must live in accordance with them. Social errors are frequent at first but are often easily forgiven by one's hosts, who recognize the foreign anthropologist as being in a childlike condition of ignorance but growing in poise under their instruction. Each social blunder in participant-observation is a learning experience pointing to a cultural difference between the anthropologist's and the hosts' cultures. As time goes on, errors become fewer and competence grows.

The lengthy period scheduled for participant-observation fieldwork, typically at least a year, allows initial impressions to be tempered, enriched, and corrected as familiarity with the local way of life deepens. It also allows a growing rapport that, under the right conditions, matures into a state in which the anthropologist's presence becomes so familiar to people that they behave more naturally. For this reason, in spite of its relatively high reliance on subjective feelings of empathy, participant-observation is arguably the most accurate way of understanding another culture.

Technologies of Fieldwork

Anthropologists use a wide variety of technologies to enhance what can be taken in by the senses and recorded in memory. Survey and excavation of artifacts and biological remains make use of many tools, ranging from rulers to remote sensing and geographic information systems equipment to precisely locate and map finds. Simple trowels in dry settings, and hoses in wet ones, aid the recovery of objects from the earth.

All anthropological fieldwork makes intensive use of writing, either on paper or via computer, to produce permanent records of findings, or field notes. Taking good field notes depends on purposeful observation, as true in ethnographic as in other anthropological research. Quite often, rough notes are taken during the day's labor, as much to avoid being obtrusive as to allow the field-worker to take in what is happening with full attention. In the evening, before sleep intervenes and memories are lost, rough notes are carefully transformed into full, detailed ones.

Descriptive field notes are supplemented by technologies that allow the direct capture of information. Sound recording allows exact words, songs, and linguistic samples to be collected. Photography allows the capture of settings, sites, objects, and activities. Cinematic recording captures visual action and sound together and is particularly useful for the study of dance and craft techniques. Of course, portable computers allow storage of all of these media and can run helpful applications, such as databases that store data for further analysis. Genealogical information, for example, is managed much more easily with the help of computer databases. Where there are no power grids, portable solar electric systems can be used to power this equipment.

Ethical Issues

A variety of ethical concerns surround fieldwork. For example, anthropologists must take care to collect information in the field without producing harm or discomfort for their hosts. Field-workers avoid putting informants into dangerous or awkward positions. For instance, field-workers may allow informants to remain anonymous if they desire.

Field-workers may also encounter conflicts over the ownership and study of the artifacts, biological specimens, and even ethnographic data they collect. The populations under study, as well as people acting as their descendants or representatives, may challenge researchers. To ensure that local groups' approval is secured and respected, it is vital that proper permits be obtained and that those groups be consulted and involved in the research.

Objectivity, Subjectivity, and Intersubjectivity

All anthropological research requires acute attention to perspectives as an integral part of its system of knowledge, or epistemology. In the field, this attention takes the form of an awareness of multiple points of view, guiding assumptions, and purposes.

From the perspective of the researcher, there are three possible epistemological stances, each with its own strengths and weaknesses, and each appropriate to different kinds of fieldwork: objectivity, subjectivity, and intersubjectivity. *Objectivity* refers to perceiving and describing something from as neutral and unbiased a perspective as possible in order to produce

observations that can be verified by a trained community of observers. Although objectivity can never be absolute or perfect, it is an important baseline from which to accurately and comparably measure objects, organisms, and behaviors. Objectivity is also needed to provide a factual description of what things physically exist, as opposed to imagined, abstract, or metaphysical entities. It also provides a guide for accuracy. Without a commitment to objectivity, anthropological fieldwork loses its grounding perspective as well as its trustworthiness.

Objectivity is insufficient for successful fieldwork, however, because it enforces a distance between researchers and researched, serving as a barrier to empathy. Self-consciously engaging their own subjectivity, researchers can draw on their own background and interests to allow a more emotional and value-based engagement. Using *subjectivity* in the field, one interprets observations with the help of personal feelings or opinions, which provide one with a more meaningful and artistically expressive connection to the objects and subjects of research. While unbridled subjectivity can allow observers to lose touch with the reality before them, measured and self-conscious subjectivity can deeply enrich the humanistic engagement of researchers with the topic or people under study. Indeed, since even the most objective observation is tinged with subjectivity, field-workers strive to know their own biases.

While elements of both objectivity and subjectivity are involved in all the field methods, a third mode of engagement characterizes direct communication and participant-observation. This mode is *intersubjectivity*, or the mutual engagement of two or more subjective perspectives in conversation or activity. Intersubjectivity is self-consciously used as a field method to remind researchers that their individual informants are, like the researchers, perceiving their world from unique perspectives meaningful to them. Intersubjectivity is a valuable method to communicate the meaning systems of conversation partners in a way that helps to preserve their emotional tenor.

The theoretical perspective of a researcher profoundly influences what questions are asked and what field methods are employed. A theoretical interest in how environmental factors influence behavior would direct the field-worker to observe and measure these factors in quality and quantity. On the other hand, a theoretical interest in how local value systems influence

choices would necessitate interactions with people to access, relate to, and describe their inner states.

Through anthropology we study ourselves by learning how we compare to others: our ancestors, other peoples and cultures, and our cousins in the animal kingdom. The range of field methods reflects anthropology's effort to understand humanity from within and without, in both its broadest outlines and its most particular manifestations.

who seek explanation and/or interpretation of human behavior, practices, ideas, and values. Conducted in the naturalistic setting of everyday life, ethnographic fieldwork lasts from months to years as ethnographers immerse themselves in the social interaction and cultural scenes of a social group.

Ethnographic fieldwork involves either applied or basic research goals. For the latter, a researcher investigates a group, a previously unexplored topic, or one that has changed significantly, writing publications that describe, for example, the Nuer of the Sudan and their love for cattle, or the San of southern Africa and their traditional foraging subsistence pattern. In applied ethnographic fieldwork, researchers address problems and offer possible solutions to a limited set of issues. For example, if a team is hired to investigate the consequences of a flood, they may use available statistical data on land and households and survey research in addition to ethnographic fieldwork, and then make recommendations for policy decisions to a government agency.

Ethnographic fieldwork includes quantitative and qualitative data collection techniques based on participant observation and ethnographic interviews with key informants. Together, these form methodological checks and balances so that data gained through observation are checked as the researcher participates in the culture and conversations with informants proceed to greater intimacy. Similarly, interview data are evaluated and compared with those gained in participant observation and also are compared from informant to informant. Ethnographic fieldwork has been described as a series of stages, from the excitement and culture shock of the initial period through the development of rapport and reciprocity with informants to the final sadness of departure. Some cultural anthropologists continue ethnographic fieldwork on repeated visits over lengthy periods and establish long-term relationships with those they study.

In the 19th century, social (or cultural) anthropologists usually did not directly collect data in the field. They relied on the accounts of explorers, travelers, and missionaries, compiling them into comparative frameworks for "scientific" purposes. An exception to this pattern was Lewis Henry Morgan, who visited the Iroquois and collected information about kinship. The change to firsthand direct data collection by anthropologists in the field is generally attributed to Franz Boas for the Americanist tradition and

FIELDWORK, ETHNOGRAPHIC

Ethnographic fieldwork is an in-depth localized research process aimed at the description and analysis of cultural systems. Both scientific and artistic in perspective and approach, ethnographic fieldwork is characteristic of the work of cultural anthropologists

Bronislaw Malinowski for the British. Even before emigrating to the United States, Boas fulfilled his dream of living among the Inuit and studying their understanding of landscape and geography. From his position at Columbia University, Boas trained many anthropologists to do ethnographic fieldwork as he did among the Kwakiutl. His initial emphasis was on “salvage” ethnography in order to preserve cultural traditions before they disappeared. On the other hand, Malinowski’s interest was in observing the society as it then worked, using the Trobrianders’ language in order to understand their point of view. By the second quarter of the 20th century, ethnographic fieldwork was the defining standard and practice for sociocultural anthropology.

The nation of Fiji contains a large group of islands known as an *archipelago*. Officially titled the Sovereign Democratic Republic of Fiji, the archipelago contains 330 islands that sprawl over 501,800 square miles in the world’s largest ocean, the Pacific. The people of Fiji inhabit about one third of the islands within the archipelago. The two largest islands, Viti Levu and Vanua Levu, and the remaining small islands surround the Koro Sea.

Fiji divides Melanesian and Polynesian islands, with low coral atolls to the east in Polynesia and mountainous volcanic islands to the west in Melanesia. Although the islands of the archipelago form a bridge between the eastern and western South Pacific

cultures, Fiji is considered part of the Melanesian Islands. The islands are further divided, in fact, by the International Date Line, which runs across the 180-degree meridian, dividing yesterday from today.

While most people of Fiji are Indian or Fijian, some are Polynesian, European, or Chinese. Migrant communities have maintained their ancestral heritage, religion, customs, and culture. Once feared for their cannibalistic practices, these islanders have been welcomed back into the world community and look forward to a future of economic and social prosperity.

Archeological evidence has shown that peoples first settled in Fiji in the late 2nd millennium BC. A legendary Melanesian chief called Lutunasobasoba led the first settlers, perhaps from Southeast Asia through Indonesia, to Fiji. Melanesian settlers to Fiji were initially fisherman who lived in coastal areas. When they migrated inland, in approximately 500 BC, they developed into agricultural settlements. Population rates and feudalism then increased. In around AD 1000, Polynesians invaded Fiji from Tonga and Samoa, and both cultures would establish a long-term presence in Fiji. The various tribes established a hereditary chief, who was responsible for finding solutions to everyday problems. They enjoyed absolute rule and were considered sacred, not to be touched by ordinary people.

In 1643, a Dutch navigator, Abel Tasman, explored the islands of Vanua Levu and Taveuni. His description of the treacherous Fiji waters kept curious explorers away for almost 150 years. In the 18th century, British explorers would venture close enough to find additional islands that still maintained their mixed Melanesian-Polynesian populations. The Melanesians dominated the windward sides of the islands. The Polynesians controlled the interiors. A complex society with chiefs still existed.

In the early 19th century, trade attracted Europeans. By the 1830s, Fiji was overwhelmed with sailors from Australia, New Zealand, China, and the United States. They sought and most often depleted the island’s supplies of sandalwood and sea cucumbers. This trade gave Fijians access to tobacco, metal tools, clothes, and guns. Early Europeans would teach Fijians enough about firearms to soon enable inter-tribal warfare that would divide the islands.

By the end of the 18th century, Fiji was divided into several small kingdoms, and the Fijian chiefs

Women and Children from the village of Silana. Courtesy of photographer, Gwendolyn A. Ross, United States Peace Corps.

were noticing more constant tribal warfare. Ratu Ebenexer Ser Cakobau was a notable native Fijian chief, who held a shaky and sometimes disputed title of “King of Fiji.” He supported the messages being spread by the arriving missionaries, and in 1854, he converted to Christianity. Cakobau and the chiefs under his command were becoming increasingly alarmed with tribal division and constant war. He tendered offers ceding the rule of Fiji to Great Britain. In 1874, knowing that only a strong government could restore order and save Fiji, they tendered a second offer to cede the nation, and Great Britain accepted. Since Britain never fought for or conquered the islands, the relationship between Britain and Fiji was always respectful and productive. The British government encouraged a continuance of most Fiji customs and laws.

Although most customs were preserved, missionaries and the British government worked hard to suppress some Fiji practices. Cannibalism was noted from the time Europeans and missionaries first

arrived on the shores of Fiji. To the early Europeans, it was a repulsive custom and one of the reasons so many explorers and missionaries stayed clear of the archipelago. The Fijians had practiced it from around AD 500 until the late 19th century. They believed that eating a person destroyed the person’s spirit. Prisoners of war and shipwrecked sailors were brought to the village, sacrificed to the local gods, cooked, and then eaten on behalf of the gods. The custom fell out of practice after years of pressure by the missionaries and British government.

In modern-day Fiji, village land is owned through kinship. When a man dies, his possessions are passed on to his brothers. The brothers then leave this wealth to their eldest sons when they pass. All villagers are expected to contribute to the community or village.

 FIRTH, RAYMOND (1901–2002)

From his position as a professor of anthropology at London School of Economics (LSE), Sir Raymond William Firth was in a position to influence studies of Pacific anthropology while contributing to anthropological theory in many areas, but he did so most prominently in economic anthropology. Firth studied at LSE, primarily with Malinowski, though he initially wavered between becoming an economist or an anthropologist. Born in Auckland, New Zealand (March 25, 1901), Firth received his PhD from LSE in 1927, based on a dissertation on Māori economics, and then began work among the Tikopia (1928–1929), which produced multiple monographs (from 1936–1970). Firth spent 1939 to 1940 in Malaya doing fieldwork, with his wife Rosemary studying fish marketing while she studied household economics.

Firth taught in Sydney from 1930 to 1932 and in 1933 took up a lectureship at LSE, where he stayed except for many brief stints elsewhere, particularly in Sydney, until his retirement in 1968. After retirement, Firth held brief visiting professorships in a number of North American universities: University of British Columbia (1969), Cornell (1970), Chicago (1970–1971), Graduate School of the City University of New York (1971), and University of California–Davis (1974). He was knighted in 1973 and died February 22, 2002, in London.

Firth claimed to be a Marxist of sorts. His analysis in Tikopia stressed the mutual imbrication of kinship and economic relations, with economic relations as a guide and controller of religious process. In his analysis of Malay fishermen, he used careful analysis of fish market bargaining to illustrate the relationship between social structure and economic rationality, again with the emphasis on the economic motivations for social

action. Firth proposed that any adequate social theory had to have both a concept of structure and a more dynamic one of social organization emphasizing social choice and innovation. Having begun with training in Marshallian economics, Firth kept a key place in his anthropological work for economic maximizing but did recognize, in discussion and teaching, that over time, anthropology had moved from a concern with stability to an interest in conflict-based change, areas to which even dynamic maximizing activity was less relevant, and Marxism perhaps more.

Firth's work on symbolism and religion was always premised on religion being significant because it constituted important work done in society for either functionalist reasons or materialist ends. Though raised a Methodist, Firth soon abandoned any religious beliefs in favor of an almost Durkheimian perspective on religion: Thus, he initially claimed that religious trance could be said to vary along a continuum ranging from minor to major control by society, allowing no place for individual trance without attempts by others to control the spirits involved.

In an area of recent interest, the relationship between informants and anthropologists, Firth contributed an early and insightful article on his key informant in Tikopea, Pa Rangifuri. The article discusses Firth's relationship and friendship with his informant, the latter's biographical development over the course of 20 years, and, more generally, Tikopian attitudes toward Firth and the informant.

As a teacher, Firth had quite possibly even more influence than as a researcher. He emphasized detailed ethnography, a preference for process over structure, and the study of social organization firmly anchored in the material economy, with concomitant divergences from ideal rules. Despite or because of structure, people had much work to do on multiple levels.

FOLK CULTURE

To fully understand the concept of folk culture, we must first separate the two words and define them individually, then rejoin them to completely comprehend the term's overall concept.

Folk, or *folkways*, are routine conventions of everyday life. They are the customary ways that people act: eating,

personal hygiene, dressing, and so on. Folkways are actions and customs that are of little moral significance; they are often matters of personal taste.

Culture is a characteristic of societies, not of individuals. Culture is all that is learned in the course of social life and is transmitted across generations, determining social hierarchy. It is the learned, socially transmitted heritage of artifacts, knowledge, beliefs, values, and normative expectations that provide the members of a society with the tools for coping with problems. It also provides an individual in a society the correct and appropriate ways to eat, dress, and the language to use. Culture is also the beliefs to guide behaviors and the practices to follow, and thus it shapes and structures social life.

Folk culture exists within a society, and it is whatever a member must know or believe in order to operate in a way that is acceptable to its members; thus, they must do so in any particular role that they have accepted for themselves. Folk culture is what individuals must learn and is separate from their biological

heritage. It is the forms and means of ideas that people have in their minds, their way of perceiving, relating, and otherwise interpreting these forms. It is the things people say and do, their social arrangements, and events, which are products or by-products of their society as they apply it to the task of insightfulness and dealing with circumstances.

Folk culture and folk customs are the beliefs and traditions, within a group that preserves its language, and the social order and ways of interpreting the world. They are the accumulated mores and way of life (tales) and learning of particular peoples.

One of the major aspects of folk culture is the spoken word or language, as a means to communicate the core concepts within a society, the important religious and philosophical reflections on the human condition. Societal cognition and individuals' understanding of their uniqueness are a shared attribute often related through a form of symbolic language, and that symbolic language is the central feature of folk culture. Symbolic language affixes a group's culture and is the shared time and place of a people, which is endowed by nature with a desire to pursue their

Source: © iStockphoto/Calvin Ng.

personal self-interests within the society, which composes their knowledge of themselves. The ideas and concepts of societal cognition can be seen and understood by focusing on the corollary a folk culture has in its relationship to perception, reason, logic, and the way people classify objects and experiences in the world.

Folk culture is often a way a people make sense of their experience in ways that link them meaningfully to the wider world, a picture of reality based on a set of shared assumptions about how the world works. Folk culture is, in essence, the society's established symbolic frameworks, which highlight certain significant domains of social experience while rejecting others. Many folk cultures are a combination of worldviews that coexist in a single society; or a single worldview may dominate the way a society sees itself in the bigger picture. In addition, folk culture acts as a cultural device for understanding geographical features, societal landscapes, and historical backgrounds of folklore within a framework of socioeconomic and political domains.

Folk culture also explains the past-present continuum of folk traditions as seen in literature, inscriptions, artwork, and other items of material culture. Often, our analysis of pastoral and peasant societies gives us an understanding of environmental orientations and a physical reference within a given society or ethnic group.

One of the most important aspects of folk culture is folklore, and its place in the understanding of folk culture is essential to the overall concepts therein.

Folklore is the traditional art, literature, knowledge, and practice that are circulated largely through oral communication and behavioral archetypes. Most societies with a sense of themselves have possession of a shared identity, and a central part of that identity has to do with folk traditions, the things that people traditionally believe (planting practices, family traditions), do (dance, make music, sew clothing), know (how to build an irrigation dam, how to nurse an ailment, how to prepare barbecue), make (architecture, art, craft), and say (personal experience stories, riddles, song lyrics).

Folk culture flows through the realm of behavior, or more precisely, social action in which cultural forms find articulation. Thus, folk culture forms find voice in artifacts and in various states of consciousness, but these forms draw their meaning from the role they play, "its use" in an on going pattern of life, not from any intrinsic relationship they bear to one another. Folk cultural language in this sense is more than mere communications; the nature of the language as a tool

or product of folk culture structures the perception of the outside world, emphasizing certain aspects over others. Thus, folk cultural language establishes a form of communications that helps a society articulate the deeper folk and cultural meanings that define that society's development, and describes a way for members in such a society to deal with their environment. Folk cultural language is made up of the myths and legends, folktales, and folklores that define and structure societal language. Often, these elements of folk culture are interchangeable, and their features frequently overlap, but a society's folk cultural language and its elements describe actions of divine beings to explain the origins of the natural world in its past.

FOLK SPEECH

Folk speech has come to mean the continued flourishing of earlier regional dialects in an age when all people in the United States begin to speak "Americanese."

At the beginning of the 20th century, people looked down on folk speech as a remnant of a rural past that Progressive Age Americans were anxious to forget. In 1913, *Webster's Dictionary* noted that folk speech was "the speech of the common people, as distinguished from that of the educated class." It was not until the 1930s that American folklorists such as Zora Neale Hurston and Alan Lomax began a comprehensive effort to salvage what was then recognized as a rapidly disappearing American cultural resource. Folk speech is really the history of the American people enacted in a very personal

way. All regions of the country and their ethnic groups have made their contribution to folk speech, including the Hispanic influence in the southwestern United States, Arizona, New Mexico, California, and Texas. From the time American fur trappers and frontiersmen and women began to venture into the area in the 1820s, this region has affected the speech of Americans in general. This was especially so after the region was annexed by the United States after the American victory in the Mexican War of 1846 to 1948.

Anyone who has ever seen an American cowboy movie would be surprised to learn that terms like *hombre*, *lasso*, *cigar*, and *chaps* all came from the language of the first immigrants to the region, colonists who began the trek north from Mexico in 1598. The current interest in the language of the region was highlighted by the success of the 1987 movie *La Bamba*, which chronicled the story of Mexican-American pop music star Richie Valens. Even Linda Ronstadt, whose father was Mexican, contributed to the folk craze with her *Canciones de Mi Padre* (*Songs of My Father*) tour in 1988 to 1989. In 2004, the Tex-Mex music called "Norteno" established Hispanic or Latino folk speech as a permanent mark on the American cultural psyche when a hit song by Texas's Flaco Jimenez earned the ultimate cultural acceptance—it became part of the regular repertoire of the satellite radio station at Denny's restaurants.

— John Murphy Jr.

FOLKWAYS

Folkways are informal patterns of social interaction that reveal commonly shared attitudes and beliefs by members of intimate social groups. They are found in all societies and characterize subcultures such as age groups, peer groups, and professional groups, family units, or special interest groups. Folkways are typically unconscious ways of thinking and doing that are not codified as formal rules or regulations. When members of social groups deviate from folk norms, they can experience repercussions, but they are usually insignificant. Folkways are fluid. They appear spontaneously, without collaboration, and they can

quickly disappear as group membership or circumstances change. Folkways are highly contextual, but they can survive persecution and be passed down through multiple generations in traditional societies. Anthropologists study folkways as creative adaptations to change as well as persistent ways of maintaining cultural values and behaviors.

Anthropologists study folkways as both material and ideological artifacts. They can be ad hoc explanations for curious circumstances that "make sense" in particular contexts. They can be shared wisdom that doesn't quite "make sense" at all, but is convenient for the moment. Folkways are most often clever interpretations of formal religious beliefs or scientific explanations when these codified ideas fail the test of "common sense." They are the names we have for substances we smoke, the procedures we use to dry fruits and preserve vegetables, the things we collect, and the analogies employed by preachers in their sermons. Folkways are innovations and inventions to counter the effects of pests and viruses, the techniques we use to hunt and fish, and the healing arts of folk medicine.

Folkways encompass folklore in the telling of tales, legends, jokes, and even gossip. They are the emotional tone and setting in the transmitting of moral values. They are as much about the way we tell as joke as the joke itself. They are the way we learn about sex, for example, as much as what we learn about it. It is the subtlety or aggression in the way we play lawn games at church picnics, as much as the kinds of games we play. It is the generosity or the intrigue associated with sharing favorite recipes, as much as the details of the ingredients. Folkways are the manner in which we bury our dead and mourn for them.

Folkways are the kinds of items we save for rags, the balls of string we wind, and the drawers full of plastic yogurt containers we never reuse. They are the names we give our children or nicknames we give our friends. Folkways are the practice of cleaning your shovel after you use it, washing your car in the winter, and the habit of kicking your boots against the side of the cement steps to knock off the barn manure before you take them off at night. Folkways are the habits we have that make us unique to others but are not really odd to us. They "make sense." They were the way your grandmother and her friends wore their hair that wasn't quite in style. They were the way your grandfather and his friends wore their dress shirts with their new bib overalls went they went to town on Saturday

night. Folkways are the quilt designs, quilting bees, and quilt auctions held in country churches in Iowa.

A classic example of an academic analysis of a folkway is the study of the transformation of the British version of cricket by the Trobriand Islanders off the coast of Papua, New Guinea. The game was introduced by missionaries as a substitute for local warfare between villages a century ago. The new game has expanded the teams to include all the men in each village clan. Challenging teams enter host villages in colorful parades. Players on both teams frequently interrupt the game with highly stylized dances and inventive mimics of the colonial past. The parades and dances serve as ritualistic forms of aggression. This is an example of how a sport varies across cultures according to local folkways.

FOLSOM CULTURE

The discovery in 1927 near Folsom, New Mexico, of distinctive stone projectile points in unambiguous association with bones of extinct Late Pleistocene bison provided the first widely accepted evidence for a human presence in North America greater than a few thousand years and initiated the field of Paleo-Indian studies in American archaeology. The discovery also inspired the notion that Paleo-Indians were specialized big game hunters. The points were named “Folsom points,” and the Folsom point makers were named the “Folsom culture.” Folsom points are one of the most widely recognized point types, possibly in the world, but certainly in North America.

In 1927, in their second season of excavations at the Folsom bison kill site, investigators under the direction of the Colorado Museum of Natural History’s Jesse D. Figgins and Harold J. Cook discovered fluted projectile points embedded in the ribs of a *Bison antiquus* skeleton. *B. antiquus* was thought to have gone extinct by the end of the Pleistocene, although the exact age of that event was not known until the 1950s, when radiocarbon dating placed it at about 10,000 years ago. In 1928, Harold Cook used the term “Folsom culture” to refer to the people who made and used the artifacts. By linking technologically distinctive points with extinct fauna in a deeply buried (2–3 m) sedimentary layer, the Folsom site provided a rough base upon which archaeologists could begin building a cultural-historical synthesis of North American prehistory.

The American Museum of Natural History conducted additional excavations at Folsom in 1928 under the direction of vertebrate paleontologist Barnum Brown. After the three seasons of fieldwork, investigators had found remains of about 30 bison, along with at least 14 Folsom points. Discovery of the Folsom site was soon followed by the first excavations of a Folsom bison kill- and camp site near

Folsom points (University Museum catalog numbers 36-19-19 and 37-26-13) from Clovis, NM. From Boldurian and Cotter (1999: Figures 38 and 39). Drawings by Sarah Moore. Reproduced with permission of Anthony T. Boldurian and John L. Cotter.

Lindenmeier, Colorado. Here, the Bureau of American Ethnology's Frank H. H. Roberts excavated remains of 13 *B. antiquus*, along with hundreds of Folsom points and hundreds of other stone tools, such as scrapers.

The technology and morphology of Folsom points are very distinctive and are expressed with incredible consistency over a wide geographic area. Folsom points are lanceolate in shape, thin, finished with pressure flaking, very finely made, usually have ground basal and lateral margins, and are distinctive in having a long and proportionally wide channel flake removed from both faces running from the base nearly to the tip, giving them a "fluted" appearance.

Besides the finished points, the fluting process also results in distinctive point preforms and channel flakes; all three are diagnostic artifacts unique to Folsom. Occasionally, a Folsom point is found with only one face fluted. Many Folsom point assemblages, especially near Midland, Texas, also contain unfluted points that are virtually identical to the fluted Folsom points in terms of shape, size, and technology. These points are called "unfluted Folsom points," or "Midland points," after the site where they were first documented. Much less common are points made on

flakes that were shaped into a roughly symmetrical lanceolate form by minimal unifacial or bifacial marginal retouch. These points have been termed "flake points" or "pseudo-fluted" points.

Other flaked-stone tools in Folsom point assemblages include end- and side scrapers, finely pointed graters, and ultrathin bifacial knives. Rare bone artifacts include eyed needles, beads, and decoratively incised items. Other uncommon artifacts include grinding stones, stone abraders, anvil stones, worked hematite, and even jet beads. Folsom stone tools are made almost exclusively from very high quality raw materials, much of it procured at significant

distances. For example, the source of one of the end scrapers at the Lindenmeier site in northern Colorado is approximately 1,000 km to the south in central Texas.

Only a small fraction of Folsom sites have been radiocarbon dated. Uncalibrated radiocarbon dates from nine sites span a 700-year period from 10,980 to 10,250 radiocarbon years before present (rcybp). Calibrated radiocarbon dates from these same sites are older and span a slightly greater time range of 12,950 to 12,000 years before present. When Folsom points are associated with faunal remains, bones of *B. antiquus* are invariably present. The radiocarbon dates and consistent faunal associations support a Late Pleistocene age for otherwise undated Folsom sites.

Thousands of Folsom points from more than 1,500 sites have been documented. The geographic distribution of Folsom points is primarily on grasslands of the prairie and plains of west-central North America. This distribution reaches from Alberta and Saskatchewan to Chihuahua and southern Texas, and from eastern Oregon and eastern Arizona on the west to Minnesota, Wisconsin, Illinois, western Indiana, and the eastern parts of Missouri, Nebraska, Oklahoma, and Texas on the east. Physiographic

Folsom points (Texas Memorial Museum catalog numbers, clockwise from upper right, 937-18, 937-27, 937-59, 937-28, 937-12) from Clovis, NM. From Sellards (1952: Figures 25). Drawings by Hal Story. Reproduced courtesy of University of Texas Press.

provinces included in the Folsom range are the Columbia Plateaus, Northern and Southern Rocky Mountains, Wyoming Basin, Colorado Plateaus, Basin and Range (including eastern Great Basin section), Great Plains, and Central Lowland.

Folsom sites include camps, bison kills and butchery sites, and stone quarry workshops. Sites of all kinds tend to be small in size and in the number of artifacts they contain; Lindenmeier is a notable exception. The numbers of bison represented in kill sites also tend to be small (on the order of 5 to 8), although one site, Lipscomb, in Texas, contained the remains of over 50 bison.

Folsom culture is generally thought to have been characterized by a highly mobile lifestyle necessitated by a reliance on bison for most food, clothing, and shelter needs. Folsom culture is viewed as analogous to highly mobile historic-era Plains Indian cultures that hunted seasonally migratory bison herds. This view is supported by the consistent presence of *B. antiquus* remains in sites that contain any faunal remains and

Source: ©Art Department, CSULA.

by typically small sites with artifact assemblages characteristic of a mobile settlement strategy. Some researchers have questioned this view based on several grounds, including the frequent presence of species other than bison (for example, pronghorn, deer, and rabbit) at many Folsom bison kill sites and concerns over potential biases in the archaeological record due to better preservation and visibility of bison bones compared with those of smaller animals. But the existing faunal evidence and the correlation of Folsom site locations with bison habitat appear to support a central role for bison in Folsom subsistence and settlement.

As of the end of 2004, older and younger Paleo-Indian skeletal remains are known, yet none are documented for Folsom. It is generally accepted that Folsom point users descended from earlier Clovis point users.

Other important Folsom sites include Clovis (also known as Blackwater Draw) and Rio Rancho in New Mexico, Mountaineer and Stewart's Cattle Guard in Colorado, Bobtail Wolf in North Dakota, Shifting Sands in Texas, and Cooper in Oklahoma.

Food is any substance that can be metabolized by an organism to give energy and build tissue. Foods are made up of a combination of calories, proteins, fats, minerals, and carbohydrates. Enzymes in the mouth begin to break down sugars as food is processed for digestion. Upon entering the stomach, the acids therein separate the nutrients and useable compounds in the food in the processes of digestion. These are then absorbed into the body to become the energy source for functioning at the cellular level.

The importance of obtaining and processing food in order to live has been a driving force behind human evolution and culture history. It is hypothesized that the quest for food in the shrinking forests of Africa played a role in bipedal adaptation. Furthermore, the subsistence patterns of different cultural groups influence many of the other institutions in that society. For example, the Masai of Kenya are pastoralists who are organized in extended families that move with their herds to different grazing areas throughout the season. Ownership of cattle is transferred from father to son, and while the women care for the cattle,

they can never own them and rely solely on the men in their society for economic stability. Hunter-gatherers are societies that practice food-gathering techniques, while other subsistence strategies include production techniques such as horticulture, pastoralism, and agriculture. Industrial societies also produce food, but the distribution often involves complex economic patterns.

The process of food acquisition for any species is the most important relationship it has to its environment, and for humans, many of the other basic features of their way of life are related to the subsistence pattern practiced. Hunter-gatherers move with the seasonal pattern of abundance in cooperative bands to harness energy and products from the environment. They live in egalitarian societies, which are highly mobile and congregate and disperse depending on availability of resources, and they are characterized by a gender division of labor that works cooperatively on a large land base. Pastoralists are also highly mobile; however, their nomadic lifestyle is divided into territories defined by grazing rights. They are herders who live in a symbiotic relationship with their animals, protecting them to ensure reproduction in return for food and other products. Horticulture is the cultivation of crops using hand tools and is characterized by a variable sedentary lifestyle, in which the group moves to a new area every 10 to 15 years, depending on soil fertility. Agriculture requires intensive and continuous land use for cultivating and raising domesticated plants and animals. Though these are four distinct modes of production, societies often have a mixed economy in which they practice one or more of these food-getting systems.

Because of the importance of food for sustenance, it has become a source of symbolic representation for various other aspects of life. Certain foods are indicative of ethnicity and have become an emblem of a cultural group. For example, pasta, eggplant, and artichokes are considered Italian cuisine, while hamburgers, apple pie, and Coca-Cola are an “all-American” meal; however, more specifically, grits, fried chicken, barbecue, and black-eyed peas represent the southern United States. The foods people eat reflect not only their cultures but also the circumstances in which they eat them. For many cultures, the nuclear family is the primary economic unit of production; therefore, this group eats together to socialize and strengthen the family bonds. However, in many Middle Eastern cultures, such as the Bedouin, only the members of the

same sex may dine together, revealing important facets of the social structure. Almost universally, sharing a table is a show of goodwill. In Pakistan, the Pathans of Swat social rules of hospitality demand that even enemies must be treated like guests until they leave the border of the host's territory, where they can show aggression even to the point of murder. In some societies, such as the Trobriand Islanders, another function of sharing a meal is to publicly acknowledge a marriage. Eating symbolizes the union of a new couple and also becomes a metaphor for the act of sexual inter-

Source: © iStockphoto/Branislava Becejski.

course. Euphemisms like “to hunger for” symbolize sexual desire, and the Mehinaku of the Amazon relate the act of sex to “eating to the fullest extent.”

Food is also important in its absence when certain prohibitions and taboos are related to rank or religious restrictions. In societies with totems, eating the flesh of the clan representation is akin to cannibalism. The Arapesh of Papua New Guinea consider the pigs they raise to be like children, and so they must exchange these animals, and that process creates an ongoing relationship with other groups. Other societies, like the followers of the Jewish and Islamic religions, have an aversion to pork based on religious edicts. Ostensibly, the reason is the “filthy” habits of pigs; however, there are no bans on chicken, which have many of the same characteristics. Instead, the cause can be seen in the early ecological niche of the domesticated animals of the region. In reality, pigs are more productively efficient energy sources; however, they share the same diet as humans, so the cost to raise them is greater than the “cud-chewing” ruminants that became the staple food source of these societies.

Taboos are limitations on what foods members of a society can eat, but limitations are also placed on how much one could or should consume. Western culture places an emphasis on attaining and maintaining thinness. In America, “fad” diets have become a marketing tool, capitalizing on the consumer's desire to look

slender, even though these diets may fail to produce the promised results. Along with this trend is a rise in eating disorders caused by the pressure to conform. Anorexia and bulimia are consequences of a society in which food resources are abundant but people feel the need to starve themselves to look a certain way. By contrast, rural Jamaica is an area of limited resources, where the mark of health and wellness is a plump physique. These people are tied to a kin network, which emphasizes food sharing; therefore, gaining weight is indicative of good social relationships, and it is equated to reproductive fitness as well as personality traits like kindness and sweetness, whereas thin people are considered mean and stingy.

FORTES, MEYER (1906–1983)

Meyer Fortes was born in South Africa in 1906. He attended school in South Africa, studying at the University of Cape Town in South Africa. He went to London, where he studied psychology at the London School of Economics and Political Science. In 1930, he received his PhD in psychology from the London School of Economics. However, he moved from psychology to anthropology, and in 1932, he began his studies with Bronislaw Malinowski at the London School. Two years later, he began fieldwork in Ghana, returning to London in 1937. He became a lecturer in social anthropology at the London School of Economics. Soon, he moved to the University of Oxford, and then to Cambridge, where he became a professor and chair of social anthropology at King's College from 1950 to 1973.

Fortes was an influential British social anthropologist. He trained with Charles Seligman, Bronislaw Malinowski, and Raymond Firth, significant figures in the development of British social anthropology. He went on to work with A. R. Radcliffe-Brown and E. E. Evans-Pritchard, as well as Max Gluckman. This extensive contact with the various branches of social anthropology allowed him to bridge the divisions within the school between the more psychologically inclined, such as Malinowski, and the more sociologically prone.

In fact, Fortes began his professional career as a trained psychologist. He combined his psychological interests with the prevailing structural functionalism of the period. His major interest ethnographically was in Africa. His primary fieldwork was with the Tallensi and Ashanti, in Ghana. His work was primarily in the study of family and kinship. Fortes developed these areas to a high level, providing major theoretical contributions in lineage theory, religion, and ancestor worship. Fortes was one of the pioneers in applying field observations to the furtherance of theoretical ideas.

Fortes was also deeply involved in the introduction of the work of Émile Durkheim to British social anthropology. Along with Radcliffe-Brown and Evans-Pritchard, Fortes viewed Durkheim as a spokesperson for a new science of social institutions. Durkheim's insistence on social facts provided a means for scientific rigor in anthropology. This rigorous structural functional approach provided social anthropology with a means and rationale for seeking interpretation

for kinship systems, sacrifice, and other social collective institutions. Durkheim provided a means for uniting fieldwork and theory into a coherent theoretical statement. Each part of the system contributed to the stability of the whole.

Fortes had great influence in the overall development of British social anthropology through his position as professor and chair of social anthropology at Cambridge University from 1950 to 1973.

Fortes was a prolific writer. Among his significant works are *African Political Systems* (1940, with Evans-Pritchard); *The Dynamics of Clanship Among the Tallensi* (1945); *The Web of Kinship among the Tallensi* (1959); *Oedipus and Job in West African Religion* (1959); *Kinship and the Social Order* (1969); and *Time and Social Structure* (1970); *Social Structure* (1970, Ed.).

FOSSEY, DIAN (1935–1985)

Dian Fossey was to gorillas what Jane Goodall is to chimpanzees. Her long-term studies of Mountain Gorillas (*Gorilla beringei beringei*) in the Virunga Volcanoes of Rwanda, in central Africa, laid the basis for understanding the behavior and social life of gorillas in general, and all subsequent fieldworkers on gorillas have built upon her work.

Like Jane Goodall, Fossey was a protégée of Louis Leakey, the renowned paleoanthropologist. On the grounds that the study of our closest living relatives, the great apes, would teach us a good deal about our own past, Leakey encouraged a number of enthusiastic individuals, almost all of them female, to study these species in the wild. Fossey and most of the others were untrained, but acquired academic training during the course of their fieldwork and in this way were able

to put their own observations into perspective and so could go on to make further insights. Dian Fossey (gorillas), Jane Goodall (chimpanzees), and Biruté Galdikas (orangutans) were the three who achieved long-term observations and so have contributed most to the field.

Fossey was working as an occupational therapist in California when she met Leakey during a trip to Africa in 1963. In 1963, on his urging, she began studying gorillas at Kabara, in the western part of the Virunga Volcanoes, in the Democratic Republic of Congo (at that time called Zaire). Political unrest made this location unsafe, and she crossed into Rwanda, where she set up a new field station at Karisoke, in the central part of the Volcanoes. (The Virungas span the borders of Democratic Republic of Congo, Rwanda, and Uganda). Here she stayed, on and off, for the rest of her life. She was devoted to Robert Hinde, her academic mentor in Cambridge, but was always anxious to be back in Rwanda.

Her contacts with gorillas become very close and intimate, and adults as well as youngsters would approach her, touch her, and sit by her while she wrote her field notes. She devised a system of recognizing individuals by the pattern of wrinkles on their noses, which she called “noseprints,” on the analogy of fingerprints. She recorded the relationships of individuals within and between troops, and the means by which new troops are formed and established troops are inherited from father to son.

She was engaged in a continuous war with poachers, who would kill adults to sell their heads and hands as souvenirs to tourists or to capture youngsters for sale to zoos. She also constantly battled government officials who wanted to excise land from the Volcanoes National Park to plant crops, such as pyrethrum, or to graze the cattle herds there. On December 26, 1985, she was found murdered in her cabin. Two men, a camp steward who had been discharged and an American researcher, were initially arrested, but her murder was never satisfactorily solved.

Since her death, tourist visits to see gorillas in the National Park have been instituted. Dian Fossey knew about the plans and had been in two minds about this prospect, but the idea has proved a great success, earning Rwanda far more foreign exchange than pyrethrum or the cattle industry, such that during the massacres and civil war in the 1990s, the gorillas were hardly interfered with. Apart from the understanding

Source: © Bob Campbell.

of gorillas that she promoted, her enduring legacy is that the Mountain Gorilla still survives and flourishes to this day.

— Colin Groves

FOSSEY, DIAN

The tragic death of Dian Fossey in Rwanda on December 26, 1985, was not completely unexpected. By the 1980s, poaching, the illicit hunting of African wildlife for profit, had become one of the world's largest clandestine businesses, making poaching not far perhaps from the smuggling of drugs as a major industry in third-world countries. With the beginning of her private war against the poachers, Fossey had made herself vulnerable to those who sought, with AK-47 assault

rifles, to harvest profits from her beloved silverback gorillas. Fossey had been hired by the pioneer African paleontologist Louis Leakey to study the gorillas because he felt they were important to his study of early man in East Africa. He and his wife, Mary, virtually created this field by their own endeavors, with their discoveries of *Zinjanthropus* man in 1959 and *Homo habilis* in 1960.

The work of these scientists was overshadowed by the wars that broke out in Africa after African countries had been given their independence by the European powers beginning in the 1950s. The Congo, where Fossey did her work, had been wracked by war virtually since Patrice Lumumba had become the first president in 1960. Indeed, Moïse Tshombe, who led a revolt against Lumumba, forced Fossey from the Congo; it was after that she made Rwanda her base for her primate studies. Nine years after Fossey's death, 800,000 people were killed in 1994 alone in Rwanda in a bloody civil war between the Hutu and Tutsi tribes. Before another decade ended, in 2004, a further 3.2 million would perish in savage fighting in the Congo itself.

The result of the fighting was that the rival armies saw in poaching a way to raise revenue for their coffers, much like the warlords in Afghanistan turned to opium to fund their incessant feuding. Thus, instead of old-time poachers with elephant guns and obsolete Lee-Enfield rifles, the new poachers were armed with AK-47 assault rifles, increasing the speed and efficiency with which they could kill the endangered animals of East Africa. The massive poaching also had its effect on wildlife in Kenya, particularly on the majestic elephant herds, where Mary and Louis Leakey's son Richard carried on the family work.

In Kenya, according to an interview with Richard Leakey in 2001, the British *Guardian* newspaper asserted that "deserters from war-torn Somalia had wiped out 85 percent of the [elephant] herds in a few short years." Leakey had left paleontology to take over the Kenyan wildlife services and had pursued his fight against poaching with all the zeal of Fossey. The *Guardian* wrote, "Leakey was ruthless, and brilliantly successful. He raised £100 million overseas and instructed his rangers to start shooting poachers instead of tracking them. In one of the world's poorest countries, he torched millions

of pounds' worth of stockpiled ivory, and lobbied successfully for a world trade ban. For the first time in over a century, African elephant numbers began to rise."

However, Leakey paid a high toll for his zeal, although he survived, unlike Fossey. "He lost both legs in a plane crash (still unexplained), and was horse-whipped on the campaign trail by government thugs," explained the *Guardian*. The crash, as well as the poaching, raised some uncomfortable associations with the corruption-plagued government of Kenyan President Daniel arap Moi. Leakey had been hired by Moi, but later emerged as perhaps his chief antagonist, and could have been in danger for this reason. However, called to task for corruption, Moi was forced out of running again for president in 2002.

— John F. Murphy, Jr.

FOSSIL RECORD

The origin and diversity of life on Earth has been one of humankind's most enduring sources of curiosity. The questions of, "who, how, when, where, and why" are still widely debated. These questions cross the boundaries between science, philosophy, and religion. It is not the intent of this entry to settle this controversy. Rather, it will look at these topics from the standpoint of science based on our current level of knowledge and understanding. This entry is arranged chronologically by era. The time spans discussed are compared to their relative positions from the "recent" end of a 100-meter-long rope to illustrate the quantity of time discussed and its distance from the present. Dates presented herein are primarily from the revised stratigraphic chart of the International Commission on Stratigraphy, 2004. The abbreviation *mya* means "million years ago."

One feature of the fossil record is that preserved fossil localities increase in direct proportion to how recently the localities were preserved. In most cases, the preservation is limited to hard body parts, and these parts are often poorly preserved. However, unusually complete and well-preserved assemblages that often include soft-tissue preservation, called

lagerstätten, greatly increase the available information for the time when the assemblage was preserved. When interpreting trends in the fossil record, it is easy to infer a gradual increase in diversity through time when, in reality, the increase is merely an artifact of an increased number of fossil localities. Likewise, *lagerstätten* have nearly always contributed to interpreted “explosions” of diversity. Unfortunately, these glimpses of possibly true representations of biotic diversity are limited to one environment and one instant in time, and these glimpses usually occur tens of millions of years apart. The fossil record thus does not contain enough information to provide any degree of accuracy concerning any but the most basic trends in biotic evolution. For this reason, this report should be considered a tentative representation of our current understanding rather than a definitive statement concerning Earth’s evolutionary events.

Earth’s Origin–Hadean Era: 4,550–3,800 mya (100 to 83.5 meters)

The Hadean is the most poorly known part of Earth’s history. For much of this time, the Earth was in the process of coalescing, cooling, and continent forming. The 4.55-billion-year date for the beginning of the planet was not obtained from Earth’s rocks, but rather from meteorites and moon rocks. These sources seem to place the “solidification” of our solar system, including the Earth, at that date. Then, for a period of time, the Earth likely underwent heating, compression, and eventual landmass solidification. The name “Hadean” was actually given to this period of Earth’s history because of the tremendous heating and volcanic events that are speculated to have happened during that time. It is thought that a collision of Earth and another planetoid at approximately 4.5 billion years ago produced our moon and significantly remodeled the Earth in the process. This and other collisions kept the Earth very hot. However, it should be noted that this picture of Earth’s distant past is highly conjectural. No rock outcrops are known that date to the first half-billion years of Earth’s history. Some scientists have postulated the opposite effect, a “snowball Earth,” for Earth’s very early history, and still others have postulated an environment rich in oxygen since earliest times. Only the most widely accepted views will be presented here.

The oldest radiometric date obtained from any rock of potentially terrestrial origin is 4.4 billion years.

This date was obtained from zircons embedded in younger sedimentary rock in west-central Australia. However, no parent rock has been found, and thus the zircons could theoretically have been of extraterrestrial origin. The oldest rock positively identified as terrestrial in origin is the 4.03-billion-year-old Acasta Gneiss, found near Great Slave Lake, in northwestern Canada. Other ancient sediments include the Porpoise Cove supracrustal sequence of northern Quebec (3.8–3.9 billion years old), the Isua Supracrustal rocks of Greenland (3.7–3.9 billion years old), and Barberton (southern Africa) and Pilbara (Western Australia) greenstone belts (3.3–3.5 billion years old).

The origin of life remains a mystery. Even the search for evidence of ancient life is difficult due to the rarity and metamorphism of preserved rocks of appropriate age and an agreement on what constitutes unequivocal evidence of life. Some researchers are convinced that unusual carbon isotopes found in the Isua rocks are proof of life on Earth nearly 3.9 billion years ago. Widely accepted evidence of life on Earth is fossilized algal mats (stromatolites) dating approximately 3.5 billion years old. However, considering how life must have started, these archaea (formerly known as *archeobacteria*) were exceedingly complex organisms. They could photosynthesize, if only through the primitive Photosystem I series of reactions, and could form colonies. Several lines of research now point to an origin of life (or possibly several origins) in a relatively hot, anoxic environment such as is found today around hydrothermal vents. Such environments were purportedly common in the Hadean, and much less common since. It should also be noted that virtually all information on early life comes from sedimentary rock, and undisputed evidence of life is present in some of the earliest sedimentary rocks found on Earth so far.

The Planet Cools, and Life Thrives: Archaean Era: 3,800–2,500 mya (83.5 to 54.95 meters)

This era of geologic time occupies over one quarter of all time since the Earth was formed. It is marked by the presence of life and the absence of free atmospheric oxygen. The types of life present during this portion of Earth’s history are represented today by similar forms living in hydrothermal pools or near volcanic vents and fumaroles on the ocean floor. These life forms did not need oxygen to survive. In fact, they produced free oxygen as a form of organic

waste. It is probable that these organisms were largely responsible for the atmosphere we have today.

The beginning of the Archaean is marked by the presence of free water in liquid form. The Earth, by this time, had cooled sufficiently that seas were forming, as evidenced by the presence of sedimentary rocks. It is unknown how long prior to the admittedly arbitrary 3.8 billion years Hadean/Archaean boundary water existed on Earth as a liquid, but it is likely that seas, continents, and atmosphere had combined to create a cycle of erosion and deposition by the beginning of the Archaean. Unfortunately, this early Archaean time is also poorly represented in the rock record.

The first undisputable evidence for life on Earth is found in the early Archaean sediments of the Barberton greenstone sequence of the Kaapvaal Craton found in South Africa and the time-equivalent sediments of the Australian Pilbara Craton. These sediments have been dated at 3.5 billion years old and may have been part of the earliest recognized supercontinent, Vaalbara, between 3.45 and 2.87 billion years ago. The African sediments contain carbon-lined tubules in lava rock, and both sediments exhibit fossilized algal mats. It is speculated that the lava tubule discovery is evidence not only for life but also for the trophic behavior of that life. The tubules are purported to show the feeding habit of at least one form of life at that time, burrowing into and eating the rock itself. There is also some evidence that even at this early stage in the history of life, genetic exchange (sexual reproduction) was occurring in some organisms.

Throughout most of the Archaean era, the relatively primitive Archaea consumed carbon dioxide and produced limited quantities of free oxygen. The oxygen was then “trapped” by several oxidation processes. Most researchers agree that the early stromatolites actually represent films of Archaea that exceeded the environment’s carrying capacity, then succumbed to a mass die-off. Once most of these cells died, the environment stabilized, allowing the process to repeat, thus producing the stromatolite laminae. It is unknown how many types of Archaea lived during the 1.3 billion years when they were the most common life forms. Today, we have 3 major types of Archaea, and these show remarkably little genetic similarity to each other. In fact, each group is more closely linked genetically with other forms of life than with each other. It has been suggested that these

groups became separate life lineages at the “protolife” level, and thus true life may have arisen more than once.

At approximately 2.8 billion years ago, or approximately 1 billion years after life on Earth first appeared, a new form of life made its appearance. Cyanophyta, commonly known as *cyanobacteria*, or blue-green algae, were the earliest life forms known to produce oxygen in large quantities. The Cyanophyta accomplished this by utilization of a series of reactions, known as Photosystem II, that break water into its components. Many believe that it was the early success of the Cyanophyta that produced the relatively large amounts of oxygen in our atmosphere. In a relatively short time from the first appearance of Cyanophyta, approximately 300 million years, the atmosphere of the Earth became saturated with oxygen past the point where oxidation processes could “trap” it. Oxygen then became a significant component of the atmosphere itself, setting the stage for a major environmental readjustment.

The Planet’s Oxygen Atmosphere Arrives: Proterozoic Era: 2,500–542 mya (54.95 to 11.91 meters)

Approximately 43% of the history of the Earth is represented by the Proterozoic era. Its beginning is marked by the first appearance of “redbeds” in the stratigraphic record. These redbeds are sedimentary layers colored by oxidized iron. This worldwide oxidation of iron in subaerially exposed sediment required large quantities of oxygen in the atmosphere. The earliest occurrence of these redbeds has been dated at 2.5 billion years ago.

Although Archaea made up a significant portion of the total biomass during the Proterozoic, Cyanophyta were the dominant life forms. It was only during Vendian time, from approximately 600 million years ago until the end of the Proterozoic, that other life forms began to contribute significantly to the biomass. During the Proterozoic, an increase in the oxygen content of the atmosphere, from 1.5% at the beginning to 15% at the end, is attributed to being produced largely by Cyanophyta. It should be noted that heterotrophic eubacteria and eukaryotes are also found in the fossil record of this time period.

The Proterozoic has been broken into three subunits, the Paleoproterozoic (2.5–1.6 billion years ago), Mesoproterozoic (1.6–0.9 billion years ago), and

Neoproterozoic (0.9–0.54 billion years ago). The Paleoproterozoic is marked by the stabilization of several island continents and the significant occurrence of stromatolites. The island continents formed the supercontinent, Kenorland, and this is the most likely cause of the first recognized major ice age event. The breakup of Kenorland approximately 2 billion years ago roughly coincides with the end of this ice event. Unfortunately, even though sediments of this age are much more plentiful than those from the earlier eras, there are still large gaps in the preserved record of this time.

Of particular importance is the appearance in the fossil record of eukaryotic organisms (organisms with an encapsulated nucleus) during this time. Current interpretation is that eukaryotic organisms originated as symbiotic multiple prokaryotic cells existing within a common membrane. In the simplest model, an Archaea thermoacidophile and a nonphotosynthesizing, heterotrophic eubacterium formed a symbiosis that included a common cell membrane. Eventually, the Archaea portions evolved into mitochondria, and the eubacterium portions became nuclei. It is widely accepted that chloroplasts are evolved from photosynthesizing Archaea in a similar symbiotic relationship.

The Mesoproterozoic is better represented in the rock record than any previous period of time. Stromatolites are abundant, and fossils of eukaryotic organisms become increasingly prevalent throughout this time period. Island continents from the breakup of Kenorland were again drifting toward each other, and eventually they came together to form Rodinia, the best-known early supercontinent, approximately 1 billion years ago. During this time, life forms capable of genetic exchange and sexual reproduction became common. Broad diversity of eukaryotic organisms, especially phytoplankton, is observed in the Mesoproterozoic of 1.1 billion years ago. Evidence of the first life on land, in the form of fungus (or possibly lichen), also exists from this time. However, possibly coinciding with the beginning of a major ice age, a decrease in observed diversity exists in sediments from that age to those from the end of the Mesoproterozoic and into the Neoproterozoic. The timing of this decrease in biodiversity begins roughly 100 million years earlier than the observed first advance of the glacial ice, so a more likely explanation is that a yet unknown environmental factor caused the decrease in biodiversity, which may also have led to a later

glacial event. A third possibility is that these two events are unrelated and the timing is merely coincidental.

During the Neoproterozoic time, life complexity increased. Spongelike animals appear in the fossil record of this time. A major series of glaciations, the Varanger glaciation event, took place between 950 and 570 million years ago. It seems likely that major ice events occurred at approximately 800, 700, and 600 million years ago. At least three separate glaciation events have been documented between 750 and 600 mya. The first firmly documented extinction and evolutionary bottleneck event occurred during this time. This extinction records the loss of nearly 70% of then-living species approximately 650 million years ago. It is unclear to what extent the extinction event was related to the ice age environmental changes. The glaciations included continued cold (to -40 degrees average global temperature) for tens of millions of years. It is also thought that ice covered over 80% of the Earth's surface at times and that the only reason temperatures were able to moderate was due to an extreme greenhouse effect caused by carbon dioxide buildup. In any case, this extreme event was accompanied by a greatly reduced diversity of life during that time.

This point in geologic time also marks the reassembly of the subcontinents from the breakup of Rodinia into the new supercontinent of Pannotia. Pannotia is difficult to describe in both its extent and duration, since some portions were assembling while other portions were breaking apart. This process continued into the Cambrian. The major assembly of land masses during this process seems to have occurred during the latest Proterozoic.

The later portion of the Neoproterozoic is remarkable for the metazoan life diversity. The last period of the Proterozoic era is the Vendian period. It is rocks of Vendian age that contain the Ediacaran fauna of Australia and similar specimens from elsewhere around the world. The Ediacaran fossils include abundant precursors to corals, worms, sea-pens, and many forms that are difficult to classify. The Ediacaran fauna lived at least 20 million years after the Varanger glaciation, and the diversification of life that occurred during those 20 million years is impressive. Tissue-level organization of life is abundantly represented in the Ediacaran fauna, and organism-level organization of life is also represented. Although many of these animals seem unrelated to known forms, others appear to be primitive arthropods, cnidarians,

molluscs, echinoderms, and possibly chordates. There is little, if any, preservation of hard body parts in these animals, and it is thought that these fossils represent only soft tissue preservation. However, the most common rock in which these specimens are preserved is sandstone, usually a very poor preserver of soft tissue.

**Life Becomes Complicated: Paleozoic
Era: 542–251 mya (11.91 to 5.52 meters)**

The Paleozoic era is marked by the appearance of animals with hard body parts and ever-increasing complexity. The boundary of the Paleozoic era is determined by the lowest occurrence of the complex trace fossil, *Trichophycus pedum*. This trace occurs lower than any other known complex trace fossil, and it is found globally at or below the first occurrence of shelly fossils. This boundary is unusual in that it is not associated with an extinction event. Vendian-type fossils are commonly found above the boundary, together with the remains of animals with hard body parts.

The Paleozoic era, especially the Cambrian period, is noted for its “explosion” of life diversity on Earth. For nearly 90% of Earth’s history, life had remained simple and had barely achieved organism-level complexity. Then, all of a sudden, complex organisms abound in the fossil record.

The Paleozoic era is broken into six periods, each containing a different set of dominant life forms. Increasing complexity of organisms correlates with increasing diversity of organisms, and various groups appear, dominate the environment, and then give way to other types of organisms in comparatively short periods of time. Since most of what is known concerning the events leading to the current biodiversity of Earth occurred during this time, it is appropriate to discuss these biotic events by period rather than era. This pattern will be followed through the Mesozoic and Cenozoic eras as well.

**Cambrian Period: 542–488 mya
(11.91 to 10.73 meters)**

The Cambrian period was a time of warm climates worldwide and diverse flora and fauna in marine environments. Climate was, from all indications, moderate, and there is no evidence of polar ice during this period. Several localities of unusually fine fossil preservation, including the Chengjiang Locality of China, dated at 535 mya, and the Burgess Shale Locality of British Columbia, Canada, dated at 525 mya,

provide much of the data from which the current understanding of metazoan origins and early evolution is obtained. Terrestrial flora and fauna, as far as is currently known, consisted only of algae and possibly lichen. The dramatic increase in complex life forms found in marine environments was not initially mirrored in terrestrial environments.

Arthropods, in the form of trilobites, dominated the Cambrian seas. These “water bugs” were equipped with many “legs” for mobility and eyes for sensory input. Other animals, such as the 2-meter-long anomalocarids, also seem to be early arthropods or at least their close relatives. By the end of the Cambrian, arthropods had diversified, and early representatives of the chelicerates, crustaceans, and arachnids appear in the fossil record of this time.

Other animals, including representatives of nearly all current phyla and of several extinct phyla, are also represented in the Cambrian fossil record. Chordates such as segmented worms and conodonts appear and diversify, providing the first major step up the ladder of vertebrate evolution. More important, the appearance of two early jawless fish from a recent discovery in China attests to the presence of true vertebrates in the mid-Cambrian. These agnathans, one resembling the lamprey in body design and the other resembling the hagfish, indicate a relatively broad diversity in Agnatha by that time. This diversity suggests that vertebrate origins had to have occurred at least in the early Cambrian and may have occurred in the Neoproterozoic.

The end of the Cambrian period is marked by a major extinction event. The loss of taxa during this event included many brachiopod, trilobite, and conodont species. This extinction event seems related to a cooling of the ocean, possibly due to a relatively localized glaciation event. It is speculated that the faunal losses at that time were of warm-water species unable to tolerate a cooler environment. However, most of the evidence available indicates that mean temperatures could have altered only a few degrees, and the cool period was of short duration. These data suggest a minor, short-lived fluctuation that had a great effect on specialized organisms that were not able to adjust to these relatively minor fluctuations.

**Ordovician Period: 488–444 mya
(10.73 to 9.76 meters)**

The early Ordovician is characterized by an increase in faunal diversity similar to that seen in

the Cambrian. By the end of the Cambrian period, approximately 200 marine invertebrate families are represented in the known fossil record; by the end of the Ordovician, that number had increased to 500. Animals appear abundantly in the Ordovician that were unknown or of minor importance in the Cambrian biosystem. These animals include corals, crinoids, bryozoans, foraminifera, graptolites, agnathans, eurypterids, bivalve molluscs (the alternative spellings of *mollusks* and *molluscs* are commonly used, though probably not correct), and nautiloid cephalopods. Ordovician trilobites were, for the most part, significantly different from their Cambrian counterparts in having developed bizarre spines and other specialized structures.

Significant terrestrial flora and fauna were present for the first time during this period. Very few Ordovician terrestrial fossil remains have been recovered, but those that have been suggest the presence of a developed terrestrial biota. Fungi have been identified from macrofossils of this time, while embryophytes have been identified from spores. Arthropod trackways are also documented from terrestrial sediments from the Ordovician.

Two significant geologic events occurred during this period. Extrusive volcanics of the Appalachians and large volcanic ash deposits suggest that volcanic eruptions of both types occurred that were possibly the largest single event of each type to have happened at any time during the Phanerozoic (Cambrian through present). These events may have been largely responsible for the significant cooling and glaciation of the end of the Ordovician and early Silurian periods.

The end of the Ordovician is marked by paired extinction events, most likely caused by extensive glaciation. The first is a drastic sea level drop, and the second, occurring approximately 500,000 years later, is a significant rise in sea level. Faunal counts across this extinction zone indicate that up to 85% of species on Earth became extinct during that time, making this extinction second only to the Permian/Triassic extinction in terms of numbers of species lost. The most likely explanation for these events is that the ocean levels dropped while ice sheets were building and advancing, then rose when the ice melted. The extinctions are thought to have been caused by marine animals not being able to adapt to the shallower and later, deeper environments to which they were subjected.

Silurian Period: 444–416 mya (9.76 to 9.14 meters)

The beginning of the Silurian period was a time of slowly moderating cold worldwide. However, during the period, the Earth's climate stabilized, and the run-away hot and cold cycles seen earlier in Earth's history have not been seen since. This moderation in temperature produced a subtropical climate over much of the Earth, but glaciers did occur above 65 degrees paleolatitude. Areas of arid landscape were common near the equator, and the equatorial seas were generally warm and shallow.

This environmental stabilization provided near-ideal conditions for another increase in diversity and complexity of life. Coral reefs became common for the first time. Brachiopods made a strong comeback after being decimated in the Ordovician-Silurian extinctions, comprising approximately 80% of the total known hard-shelled species by midperiod. Stromatoporoids and bryozoans contributed significantly to reef building, as do calcareous algae. Graptolites, conodonts, molluscs, and crinoids were also common. Trilobites were not as diverse as they were in the Cambrian and Ordovician, possibly because of the increase and diversity of eurypterid species. Jawless fish became widespread and diverse, and the period also marks the first of both freshwater fish and fish with jaws. Eurypterids, xiphosurans, and scorpions are also found in freshwater sediments of this period.

The first good evidence of life on land is seen in Silurian sediments. Discovered remains include relatives of spiders and centipedes and the earliest fossils of vascular plants. Most vascular plant fossils found have branching stems and no leaves. However, a lycophyte, a plant with leaves and a fully developed vascular system, has been reported from Australia.

The end of the Silurian is unusual in that it is not marked by a significant geologic or extinction event. The marker used to separate the Silurian and Devonian is the first occurrence of the graptolite, *Monograptus uniformis*.

Devonian Period: 416–359 mya (9.14 to 7.89 meters)

The Devonian period saw the continued rapid evolution and diversification of both plants and animals. The Devonian is known as the "age of fishes" because of the virtually simultaneous appearance of precursors

of all living groups of fishes and groups now extinct. However, plants experienced a similar radiation, and the first land vertebrates, insect precursors, and terrestrial spiders appeared. In the seas, ammonites made their first appearance, as did siliceous sponges. Brachiopod and coral diversity reached its peak, but trilobite diversity was declining.

The fossil record of the Devonian includes a broad diversification of jawed fish. Placoderms, acanthodians, sharks, and bony fish are all well represented. An extinction event between the middle and late portions of the period seems to have provided an opportunity for shark and bony fish evolution by removing many of the placoderms. The extinction occurred during a period of relatively uniform, warm climatic conditions, and many animal and plant groups were unaffected. Its severity (70% of known species) primarily represents the decimation of benthic, shallow marine species.

The most significant events of the Devonian occurred as both animals and plants began to occupy terrestrial environments. Terrestrial plants including lycopods, ferns, and horsetails appeared, and by the end of the period, woody, treelike lycopods up to 30 meters tall were common. By the end of the Devonian, seed-bearing plants had developed, although their colonization of drier, more inland habitats would come later. Insects were likely common at this time. However, the only fossil insects known from this period are springtails. Lobe-finned fish evolved that were equipped with both gills and lungs. They also had fins that resembled legs. It is thought that these adaptations were of benefit to survival in shallow marine environments. By the end of the Devonian, this lineage included true amphibious forms capable of walking on land for extended periods. This transition placed these vertebrates into an environment where eurypterids, arachnids, and primitive insects already existed.

Ironically, the terrestrial conquest by plants during the last portion of the Devonian may have been the cause for the extinction event that marks the end of the period. The end of the period is marked by slow cooling, increased atmospheric oxygen, and a decrease in atmospheric carbon dioxide. Terrestrial plants accelerated the formation of soils, thus accelerating the weathering of silicate rocks. The calcium and magnesium released, coupled with a significant increase in terrestrial photosynthesis, provided for significant additional removal of carbon dioxide from

the atmosphere. The loss of this greenhouse gas concentration, in turn, allowed the Earth to cool by several degrees. Although the cooler environment did not immediately remove species from the system, apparently it hindered evolutionary adaptation and replacement. Thus, the Devonian extinction event was gradual, with species being removed from the system and not being replaced, rather than following the more catastrophic pattern seen in earlier extinctions.

Carboniferous Period

(Mississippian + Pennsylvanian):

359–299 mya (7.89 to 6.57 meters)

The Carboniferous period was first described in England and referred to the lowest occurrence of extensive coal deposits. In North America, the same geologic strata were broken into two periods, the Mississippian and the Pennsylvanian. The Mississippian period featured extensive limestone, as the North American continent was mostly underwater during the entire period. The Pennsylvanian saw a lowering of sea levels and the formation of lowland, deltaic forests that were intermittently inundated by marine transgressions. For the geologic timescale to be applicable worldwide, some arbitrary “tweaking” of the units has made the Mississippian and Pennsylvanian of North America match the Lower and Upper Carboniferous of Europe, respectively. This shift has relegated the Mississippian and Pennsylvanian to an unnamed subperiod status.

The forests of the late Devonian gave way to low-lying shrubs in the early Carboniferous. Sea levels became high worldwide, and much of the Devonian forested land was inundated. The first truly terrestrial tetrapod vertebrates show up in the fossil record. Euramerica is tropical and equatorial, and life flourished in terrestrial, aquatic, and marine environments. It was during this time that the earliest known “reptile,” *Hylonomus*, appears. It should be here noted that the term *reptile* is a catchall that contains representatives from several lineages and excludes their descendants, the mammals and birds. The appearance of *Hylonomus* places the origin of the amniotic egg in the Early Carboniferous. As the seed allowed plants to become separated from aquatic environments, so the amniotic egg allowed vertebrate animals to become so separated. It is a still unresolved mystery why animals with this obvious advantage did not become diverse and prevalent until more than 50 million years later.

In the oceans, the placoderms, so diverse in the Devonian, are missing from the Carboniferous record. Chondrichthyan have become diverse and were the top predators in the environment. Echinoderms, in the forms of crinoids and blastoids, became extremely common, and their calcareous skeletal structures add significantly to the limestone sediments of this period. Graptolites became extinct, and trilobites were reduced to one type.

By the late Carboniferous, the ocean levels alternately rose and lowered as Gondwana became covered by glaciers. Euramerica remained subtropical, and coal swamps became commonplace. Forests once again covered large areas of the Euramerican landmass. These forests consisted of diverse plants including 15-meter-tall tree ferns; *Calamites*, a giant version of the modern “horsetail” plant; *Lepidodendron*, a 30-meter-tall lycopod; seed ferns; and primitive conifer-like plants that reached 40 meters in height. These extensive forests eventually produced most of the coal on Earth today. Flying insects arrived, including cockroaches resembling those of today and dragonflies with 70-centimeter (2-feet) wingspans. Bony fish inhabited lakes and streams as well as marine environments. Many types of tetrapods were present, including representatives of virtually all amphibian groups and the precursors for the anapsid, synapsid, and diapsid amniotes. By the end of the Carboniferous, the supercontinent, *Pangaea* (the commonly used spelling, *Pangea*, is incorrect), had formed, and its formation contributed to a warming and drying trend that carried through into much of the Permian. No major extinction event is associated with the Carboniferous/Permian transition, but the coal beds disappear as the climate became warmer and drier.

Amniote origins and evolution has its roots in the Carboniferous period. However, the order of appearance of specimens in the fossil record does not match the current understanding of amniote evolution. It is thought that amniotes diverged into two groups, those in the synapsid lineage leading to mammals and those in all other lineages, very close to the point of amniote evolution itself. This would put the divergence somewhere in the early Carboniferous, no later than 325 million years ago. The second separation that is postulated to have occurred is that of the anapsids, the lineage leading to turtles, branching off nearly as early as that of the synapsids. Finally, the diapsid lineage leading to birds would branch off. However, in the fossil record, diapsids appear first, in

the mid-Carboniferous; the synapsids appear next, in the Upper Carboniferous, and the anapsids appear last, in the mid-Permian. While it is certainly possible that these lineages did exist but have not been discovered in the fossil record, it is unsettling that the postulated evolutionary pattern is reversed in the known record.

Permian Period: 299–251 mya (6.57 to 5.52 meters)

The Earth during the Permian period experienced a varied climate, from glaciers in the south to swampy forests at the equator. As time progressed, the glaciers receded, and the equatorial areas became much warmer and drier. The large landmass of Pangaea likely interfered with the normal climate mitigation from the oceans. As a result, deserts and hypersaline inland seas were common. In fact, most of the Earth’s salt beds were laid down at this time. During this nearly 50-million-year sequence, climatic fluctuations and increased loss of shallow sea environments precipitated the largest extinction event in Earth’s history, the Permo/Triassic extinction. However, throughout the entire 50 million years of the Permian preceding the extinction, marine habitats were dwindling, and species diversity within families of marine animals was lessening. All marine animal groups, with the possible exception of the conodonts and fish, showed a marked decline in diversity throughout the Permian.

During the early portion of the Permian, amphibians such as anthracosaurs and cotylosaurs were competing with early synapsid reptiles for terrestrial dominance. However, amphibian diversity dwindled throughout the Permian. Although the Permo/Triassic extinction event had little effect on the amphibians, only a few forms survived into the Triassic. Pelycosaurs, including the sail-backed *Dimetrodon*, became the largest terrestrial predators. In a parallel evolution, *Edaphosaurus* and caseid pelycosaurs became the first large plant-eating amniotes, some reaching over 4 meters in length. In the mid-Permian, pelycosaurs disappeared, to be replaced by very large-headed but much more mammal-like therapsids. These therapsids are thought to be closely related to the pelycosaurs, but more specialized. In turn, the therapsids were out-competed by one of their daughter lineages, the theriodonts, during the late Permian. This new lineage of mammal-like reptiles, including dicynodonts, gorgonopsids, therocephalians, and cynodonts, most likely included the first warm-blooded, furry animals.

These groups, with the exception of the gorgonopsids, survived the Permo/Triassic extinction and were prominent in the early Triassic terrestrial ecosystem as well. Diapsid reptiles also made their appearance in the Permian, and the late Permian diapsid, *Coelurosauravus*, is the earliest known vertebrate capable of flight.

A series of relatively rapid fluctuations in temperature and moisture seems to have been the driving force behind a significant floral turnover during the Permian. Moist, tropical plants gave way to gymnosperms and seed ferns capable of withstanding a much wider range of climatic conditions. However, at the Permo/Triassic boundary, floral changes occurred rapidly. In some areas, gymnosperm forests were wiped out and lycopods took over, while in others, gymnosperm forests appeared. In most cases, the pattern observed throughout the Permian was disrupted at the Permo/Triassic boundary. Even where gymnosperms remained the dominant floral component, there was a species turnover, and the preboundary forms are not the same as those preserved after the boundary event.

The Permo/Triassic extinction event is identified as the most serious extinction of life ever in Earth's history. Approximately 90% of known marine species and nearly half of terrestrial species were lost. Several factors have been suggested as the cause of this catastrophe, including global trophic collapse, meteor impact, rapid climate change, anoxia, supercontinent formation, glaciation, and both explosive and nonexplosive volcanics. Unfortunately, there is seldom a single cause for any worldwide event. It appears that all the previously listed factors affected the Earth's biosphere at or near the Permo/Triassic boundary. No single factor has yet been identified that positively correlates with every major extinction event in the Phanerozoic, and the Permo/Triassic is no exception. Perhaps the key to this event is in the universality rather than the exceptions concerning this event. The Permo/Triassic extinction event is concurrent with meteor impacts, a supervolcano explosion, huge volcanic flows, climate fluctuations, a supercontinent, and food chain collapse. It may be, indeed, that the reason for this biggest extinction even in Earth's history is the concurrent series of events, rather than any single event.

**Dinosaurs Rule: Mesozoic Era:
251–65.5 mya (5.52 to 1.44 meters)**

The Mesozoic era was a time when the last major groups of animals and plants evolved. It is broken

into three periods: the Triassic, Jurassic, and Cretaceous. The Mesozoic was, generally, a time of uniform warm temperatures and subtropical climates. However, the Permo/Triassic extinction radically altered the roughly steady progression of evolution and diversity of life on Earth. Wonderfully complex and interdependent reef communities were reduced to a few simple forms, and 250 million years later, reef communities were still relatively primitive compared with their previous complexity.

**Triassic Period: 251–200 mya
(5.52 to 4.40 meters)**

Nearly total devastation in the marine environments coupled with hot, dry conditions over most of the terrestrial landscape made the early Triassic period relatively inhospitable. Although Pangaea is still intact, major ecological provinces are observed in the fossil record. These provinces seem to coincide with Laurasia versus Gondwana. However, these two subcontinents were joined by the early Permian and did not separate until the beginning of the Cretaceous period, some 150 million years later. Why such ecological provincialism existed is unknown.

The two main marine environments were the deep-ocean Panthalassic Sea, which surrounded Pangaea, and the shallow, warm Tethys Sea, which was mostly surrounded by Pangaea (the Mediterranean Sea is a remnant of the Tethys). The seas supported a wide variety of chondrichthyan and osteichthyan fish, cephalopods, molluscs, and brachiopods. Marine reptiles, including ichthyosaurs, also made their appearance for the first time. However, this did not occur immediately after the Permo/Triassic boundary. Both seas exhibited anoxic conditions immediately, and for several million years after, the Permo/Triassic event. In addition, data suggest that the ocean chemistry included high levels of carbon dioxide and hydrogen sulfide during this time as well. Atmospheric oxygen was also depleted to its lowest levels in the Phanerozoic. Life seems to have maintained (and in some cases even flourished) only in isolated habitats during that time.

On land, amphibians made a brief comeback during the early Triassic, but were replaced in most terrestrial habitats by reptiles during the mid-Triassic. Extensive redbeds appear during this time, and these have been interpreted as indicators for hot, dry climate. It has been suggested that the amphibians made a resurgence because they were tied to rivers and

streams and the water ameliorated an otherwise harsh environment. Several lineages of synapsid reptiles survived the Permo/Triassic extinction, including Cynodonts, Dicynodonts, Gorgonopsians, and Therocephalians. However, Gorgonopsians vanish from the fossil record shortly after the Permo/Triassic boundary, and Dicynodonts and Therocephalians slowly dwindle and fade out of the record. It should be noted that *Lystrosaurus*, a Dicynodont, has been found worldwide in Late Permian and Early Triassic sediments. In general, therapsids constitute roughly 90% of early Triassic terrestrial tetrapod fossils.

Diapsid and anapsid reptiles were also present, although early Triassic fossils from these groups are virtually unknown. By mid-Triassic, a diverse fauna again appears in the fossil record. It appears that in the scramble for life during those first few million years after the Permo/Triassic extinction, animals were able to diversify quickly and to survive even if they weren't very specialized. As time went on, however, those lineages whose ancestors were somewhat specialized were able to out-compete those who weren't, and the number of different lineages dwindled. By the mid-to-late Triassic, the diapsid fossil record contains rhamphorynchoid pterosaurs, proto- and true dinosaurs, crocodilians, all major swimming-reptile groups except mosasaurs and lizards. Turtles and true mammals appear in the late Triassic fossil record as well. Dinosaurs diversified very soon after their origin. By the end of the Triassic, theropod, sauropod, and ornithischian dinosaur lineages were present.

The end of the Triassic period is marked by one of the "Big 5" extinction events. A regression of the oceans followed by an early Jurassic transgression are partially responsible for the loss of certain species during that time. Also during that time, one of the largest volcanic events, the mid-Atlantic rifting, began. This rifting and volcanic activity greatly increased the amount of atmospheric carbon dioxide, and it is likely that this event also played a role in the Triassic/Jurassic extinction event. The fossil record is, however, quite incomplete from this particular point in time, and it may be that these events precipitated a protracted faunal turnover that should not properly be considered an extinction event.

Jurassic Period: 200–145 mya (4.40 to 3.19 meters)

The beginning of the Jurassic period is marked by the breakup of Pangaea into Laurasia and Gondwana.

The diversity of life seen in the late Triassic is generally seen to continue within the same groups in the Jurassic. A marine transgression covered much of the continental landmass during the early to middle Triassic. This transgression provided greatly expanded shallow marine habitat, and this habitat was soon teeming with marine reptiles, teleost and chondrichthyan fish, plankton, bivalves, arthropods, and other forms. Crocodilians were represented by species similar to the mostly aquatic forms found today.

Terrestrial ecology was dominated by a now diverse dinosaur fauna in both herbivore and carnivore roles. Cynodonts, including primitive mammals, diversified as small, insectivorous forms that did not directly compete with the larger dinosaurs. The tritylodonts survived as herbivorous protomammals well into the Jurassic. Gymnosperms and cycads were common, replacing the last of the seed ferns. Dinosaurs evolved as larger and more specialized forms throughout the Jurassic. The smaller and more generalized prosauropods of the early Jurassic gave way to the larger vulcanosaurids and cetiosaurids, which, in turn gave way to the diplodocids and camarasaurids. By the end of the Jurassic *Seismosaurus* and *Brachiosaurus*, the longest and tallest animals, respectively, to ever roam the Earth, wandered in North America. Likewise, the largest predator of the early Jurassic, *Dilophosaurus*, was replaced by the much larger *Allosaurus* by the end of the period. Smaller dinosaurs, such as *Othnelia* and *Ornitholestes*, were present at the end of the Jurassic. However, they were literally and figuratively overshadowed by the larger forms.

Birds also appeared in the Jurassic. However, these remains consist of only a few specimens of *Archaeopteryx* from the 150-million-year-old limestones of Solnhofen, Germany. The next oldest avian remains are those of *Confuciusornis* and others from 120-million-year-old sediments in China and the approximately 100-million-year-old remains of *Ichthyornis* from the chalk beds of Kansas. *Archaeopteryx* is so similar to small theropod dinosaurs that for many years, a featherless specimen was incorrectly identified as *Compsognathus*. Most researchers now believe that birds evolved from a *Compsognathus*-like small theropod dinosaur ancestor.

The Jurassic/Cretaceous boundary is the most problematic of any in the Phanerozoic. In many localities, unconformities (areas of missing sediments) are present at this level, and no identifiable marker has

been established where the sediments are present. Sea levels had dropped, but it had happened gradually. Small polar ice caps had formed, and temperatures did reach their coolest of any time in the Mesozoic. However, this “cool” period was still quite warm, even when compared with the Earth today.

It seems that the Earth experienced a faunal turnover around the time of the Jurassic/Cretaceous boundary, but it was apparently a gradual event. Animals would die out and be replaced in one habitat, while thriving for several million years longer before succumbing in other habitats. Perhaps the most visible event is the loss of most sauropod and carnosaurid dinosaurs from Laurasia at that time. Sauropods and carnosaurs continued to thrive in Gondwana but were nearly wiped out on the Laurasian continent.

**Cretaceous Period: 145–65.5 mya
(3.19 to 1.44 meters)**

The Cretaceous period is marked by yet another marine transgression. Indeed, the name, *Cretaceous*, means “chalk,” and refers to the chalk formations of the white cliffs of Dover, England. Early Cretaceous terrestrial deposits are rare. There was an approximately 20-million-year gap between the beginning of the Cretaceous period and the lowest occurrence of well-preserved terrestrial fossil remains. The most likely reason for this is that in most localities, these strata are missing.

By the middle of the Cretaceous period, designated as Aptian-Albian, the Earth’s oceans had once again receded, and a diverse terrestrial flora and fauna are present in the fossil record. Angiosperms, the flowering plants, have made an appearance, although they did not become diverse and widespread until the very end of the Cretaceous. Both marsupial and placental mammals appear in the fossil record. Saurischian dinosaurs, including *Acrocanthosaurus*, *Deinonychus*, and *Utahraptor*, and ornithischians, such as *Tenontosaurus*, *Psittacosaurus*, and *Sauropelta*, represent the wide dinosaur diversity achieved by the Middle Cretaceous.

Another marine transgression separates the middle of the Cretaceous from the late, although terrestrial sediments are preserved in some locations during this time. Late Cretaceous Earth was dominated by a broadly diverse dinosaur fauna. By the middle of the Campanian age, approximately 75 million years ago, dinosaurs had reached the height of their diversity. Mosasaurs had appeared in the oceans, and flowering plants were common, although not yet

the dominant flora. Marsupial mammals were common and diverse. From the mid-Campanian until the end of the Cretaceous, dinosaur diversity dwindled. Even though the numbers of specimens in the fossil record remain roughly equivalent, end-of-Cretaceous dinosaur fossil diversity is not nearly that of the Campanian. A few specialized forms seem to have taken the place of many less specialized types.

Undoubtedly the most famous extinction event is the one that marks the end of the Cretaceous period and the end of the nonavian dinosaurs. However, this extinction event was actually a relatively gradual turnover in flora and fauna that began at least 100,000 years before the iridium-enriched clay layer was produced and lasted for at least 300,000 years afterward. Other estimates place the beginning of the turnover at least 500,000 years before the iridium-producing event. In any case, several events occurred that would have caused at least regional biotic crises. First, mid-latitude climate on Earth changed from subtropical to temperate. Second, grass made its appearance as the dominant ground cover. Third, the Deccan Traps Volcanics were extremely active and were producing huge quantities of ash, methane, and carbon dioxide. And finally, an asteroid approximately 10 kilometers (6 miles) in diameter slammed into carbonate rocks of the Yucatan Peninsula, Mexico.

Although any one of these events may have caused the loss of significant life in Earth’s ecosystem, it is likely that it required the combination of these events to actually produce the extensive species turnover seen in both the marine and terrestrial fossil records of the Cretaceous/Tertiary (K/T) boundary. Dinosaurs, and possibly pterosaurs, were likely among the first to disappear. The highest dinosaur or pterosaur remains found to date are still several meters below the iridium layer. However, in certain ocean regions, the turnover observed in fossil plankton is restricted to a dramatic change from one side of the clay layer to the other. This signifies a nearly instantaneous event related to the impact. Taking the evidence in combination, multiple causation of the K/T event is the only viable explanation.

**Opportunity Knocks and
Mammals Answer: The Cenozoic
Era: 65.5–0 mya (1.44 to 0 meters)**

The last 65 million years or so of Earth’s history is well represented in the fossil record. It is interesting

that this last 1.5% of Earth's history has received more scientific attention than the other 98.5% combined.

Originally, all rocks and fossils of this age were labeled "Tertiary." Later, the most recent sediments were broken off into a Quaternary period. The Cenozoic era is currently divided into two periods: the Paleogene and the Neogene. This is a recent division that has replaced the Tertiary and Quaternary divisions at the level of period, and Tertiary and Quaternary have been raised to sub-eon status. This change has created a more equal period division and has placed the division at a point of major global climate change. It should be noted that the spellings, *Palaeogene*, and *Paleogene*, are both used in print. However, the International Commission on Stratigraphy uses *Paleogene*, and that spelling is thus considered proper.

**Paleogene Period: 65.5–23 mya
(1.44–0.51 meters)**

The K/T extinction event removed most life, and many species, from both terrestrial and marine ecosystems. The loss of the top predators from both ecosystems meant that other animals no longer had to hide to survive. The fossil record indicates a very rapid increase in both number of species and in individual size. The climate itself, except for a short cold spell at the K/T boundary, remained a subtropical greenhouse over most of the Earth. Glaciers were unknown until the latest Paleogene, when the Earth began a gradual cooling that continued into the Pleistocene ice age. The breakup of Pangaea continued, and by the middle of the Paleogene, nearly all current landmasses had formed. These island continents provided reproductive isolation for their respective faunas, and life evolved along different paths in Australia, Eurasia, Africa, North America, and South America.

The Paleogene is divided into Paleocene, Eocene, and Oligocene Epochs. During the Paleocene, condylarths and creodonts dominated most terrestrial environments. Although ungulates descended from condylarth ancestors, the Paleocene terrestrial herbivore ecospace belonged to the nonungulate condylarths. Likewise, ancestors of modern carnivores were present in the Paleocene, but most terrestrial mammalian predators were creodonts. A flightless bird, *Gastornis*, was also one of the top predators of the Paleocene, at least in what is now Europe.

Many of the terrestrial mammals that thrived during the Paleocene became extinct about 10 million

years after the K/T event. A major climatic event, the Paleocene/Eocene Thermal Maximum, is thought to have been responsible for this loss and also the loss of many types of benthic foraminifera. A very short-term event, measured at less than 20,000 years, saw a 15-degree rise in ocean temperatures, which affected even the deep ocean. It then took several hundred-thousand years for the temperatures to cool to equilibrium values. It has been postulated that methane "burp" caused the greenhouse conditions that raised the temperatures. Methane was, and is currently, trapped in huge reservoirs of frozen clathrate on the ocean floors. The melting of this material is thought to be a self-perpetuating reaction once started, and the reaction would end only when no more clathrate was left to melt. Some scientists believe that this is a recurring event that was the cause of the Permo/Triassic event and is the most imminent and significant threat to the current ecosystem.

By the Eocene, ungulates and carnivores were vying with the condylarths and creodonts, respectively, for their positions in the ecosystem. Also of note is the appearance in the fossil record of primitive anthropoids by mid-Eocene. Early ancestors of whales were beginning to inhabit aquatic environments, and most modern bird group origins can be traced to Eocene ancestors. A meteor impact formed Chesapeake Bay as a nearly 100 kilometer crater, and another, even larger, struck in Russia near the middle of the Eocene, but these impacts seem to have caused little harm to existing species.

By the Oligocene, the earlier forms had given way entirely to the ungulates and carnivores as the major terrestrial herbivores and carnivores. The first monkeys and apes also appear in the Oligocene. By the end of the Oligocene, Antarctica had taken up its position at the South Pole, and glaciers had formed on its surface. This positioning of Antarctica likely had much to do with the Earth's cooling. A rapid marine regression at the Paleogene/Neogene boundary was likely caused by the formation of Antarctic glaciers. The position of Antarctica is likely a major factor in the cooler-than-normal temperatures of the Earth today.

Neogene Period: 23–0 mya (0.51–0.00 meters)

The fossil record of the Neogene period generally depicts repeated adaptation to gradual, increasing cold. The four epochs of the Neogene—Miocene, Pliocene, Pleistocene, and Recent—are characterized by floral and faunal adaptations to geologically rapid

climatic fluctuations. The sediments of the Oligocene/Miocene boundary provide the first record of significant glaciation occurring above those of the early Mesozoic.

Cool temperatures and Antarctic glaciation of the early Miocene gave way to global temperatures similar to the late Mesozoic greenhouse by the middle of the epoch. Global temperatures reached an average maximum of approximately 6 degrees Celsius more than is experienced today. Although the temperatures rebounded from the early Miocene lows, temperature-sensitive plants gave way to grasses as the predominant ground covering. Toward the end of the Miocene, kelp forests appeared in the oceans for the first time, and global temperatures were gradually decreasing.

Mammals achieved their greatest diversity during the Miocene. Semi-isolation of continental landmasses allowed reproductive isolation and preservation of some less specialized groups in certain areas. Quality grazing and browsing habitats for herbivores also contributed to Miocene mammalian diversity. This diversity includes the first appearance of hominids in the fossil record.

The Pliocene was a time of cooler temperatures and drier climates. No major extinction event is associated with the Miocene/Pliocene boundary, and the flora and fauna in both terrestrial and marine environments remain largely unchanged throughout this time. The same may be said for the Pliocene/Pleistocene boundary. However, the global environment changed drastically approximately one third of the way through the Pleistocene.

The mid-Pleistocene glacial event marks the first glacial incursion into the middle latitudes since the Paleozoic. This unusually cold cycle is thought to be related to the continued location of a continent in the South Polar Region, coupled with global temperature and circulation patterns that largely block heat transport to the Polar Regions. It is thought that glaciation is somewhat self-perpetuating. As more of the Earth's surface is covered by ice, more of the sun's energy is reflected rather than absorbed. And, the less energy that is absorbed, the cooler the Earth gets and the more ice is produced.

Animals began to appear in the Pleistocene fossil record that were well adapted to cold environments. These animals include the woolly mammoth, woolly rhinoceros, elk, moose, and bison. However, the major glaciation events of the Pleistocene were relatively short-lived, lasting only a few tens of thousands

of years on average. In between these events, the Earth experienced interglacial periods when the global climate was at least as warm as that of today.

Technically, the fossil record ends with the beginning of the ice age, because more recent remains have commonly not been "fossilized." However, the depositional processes that have provided an interesting and occasionally detailed picture of Earth's history are still at work, and they continue to produce a record of Earth's life and geologic events.

What is a *fossil*? The word is Latin, and it means, "dug up." One of the earliest known research publications to use this term was Agricola's work on systematic

mineralogy, *De natura fossilium*. It wasn't until Lamarck's *Hydrogeologie* was published in 1802 that the term was restricted to "the still recognizable remains of organized bodies." Even as late as the mid-1800s, the concept of fossilization was, except in the minds of a very few, considered the result of a recent worldwide deluge. For over 1,000 years, just the discussion of events beyond the scope of the biblical account of creation could cause one to end up in prison or worse. Sir Walter Raleigh is one of the better-known of these victims. His conviction for treason and subsequent beheading was precipitated

in part by his suggestion, in his volume entitled *History of the World*, that civilization was older than the biblical account allowed. The current definition of the term *fossil* has thus only very recently evolved.

Currently, the term "fossil" refers to any remains or traces of once-living organisms. Although this definition is much narrower than the original term's Latin origin, it still covers a broad range of preserved structures. A fossil may be as simple as a single preserved mark in a sediment or as complex as a mummified dinosaur. It may be as old as 3.7 billion years or as recent as a few hundred. Fossils are as varied and diverse as the life forms that produced them and the climatic and structural conditions that preserved them. However, this vast array of preserved evidence of past life has survived to the present through only a very few natural processes. These processes include permineralization, tracks and traces, molds and casts, carbonization, and original preservation. The following is a brief examination of each of these processes and a description of the types of fossils preserved through each process.

It should be noted that one process is common to all fossil preservation: the process of protection. Regardless of the method of preservation, if the specimen had not been suitably protected, it would not have survived. Most often, this protection involves being buried and remaining undisturbed until discovery. Rapid

encasement and removal of oxygen from the environment are the key protection criteria for virtually all fossils. These conditions are necessary to keep the organic tissue from either deteriorating or becoming damaged while the other processes take place.

Permineralization and Replacement

The permineralization process is the one most often thought of when one describes fossilization. It is defined as the molecule-by-molecule replacement of the organic remains with inorganic minerals. Through this process, the original structure of the specimen is preserved even at the microscopic level. Although this process has been performed in the lab in a matter of hours, it is a process that usually takes millions of years in nature. In fact, the process is almost never carried to completion; an average of 3% to 8% of the original organic molecules remain in permineralized specimens. The preservation of hominid remains range from virtually no permineralization to almost complete permineralization. The oldest recovered DNA from hominid remains is about 70,000 years. Mineral replacement in the older specimens has progressed too far to allow DNA recovery.

The permineralization process generally occurs in two stages. The first stage happens rapidly, and the second much more slowly. The first stage in this

process consists of filling the pore spaces and cavities, and the second stage is the replacement of the tissue itself. The speed at which these processes take place is determined by heat, pressure, mineral type, and quantity available, and groundwater flow. If an animal carcass is preserved in a hot-springs environment, it will fossilize much more rapidly than if it were in a sand dune in a temperate desert. However, the fossil produced in the desert environment would likely be much stronger and more durable, since the primary mineral available would be silica rather than the carbonate usually found in hot-springs environments.

Molds and Casts

If an object such as a tree trunk or animal carcass falls into mud that subsequently hardens, the mud produces a mold. This mold preserves the exact shape of the object. If the object then deteriorates and is removed, the cavity can be refilled. This infill is a natural casting. Natural molds and casts are some of the most common fossils. Silica infilling of the mold often produces beautiful agate and jasper. Fossilized wood limb casts preserved in this manner are often displayed with a polished cross section, and such specimens are sought by jewelers and rock collectors.

Carbonization

Soft body parts are rarely preserved. When they are, it is usually through the process of carbonization. When preservation conditions are just right, the organic material present in the original specimen is converted to various gases through chemical reactions, leaving only the carbon behind. The result is a thin film of carbon that often perfectly preserves the original body shape. This form of fossilization is responsible for such diverse remains as the Cambrian sea fauna of the Burgess Shale and the Eocene plants of the Green River Formation. This process, on a larger scale, is responsible for coal.

Tracks and Traces

This form of preservation is unlike any other, in that it preserves life events rather than death events. It is also unlike any other listed here in that it is not a single process that preserves, but rather a multitude of processes through which the life event was recorded.

These remains include trackways as well as event traces, such as wing brushings, tail drag marks, nest structures, and coprolites (fossilized droppings). It is from these fossils that we gain our best estimates of speed, movement, and diet. This evidence is generally observed as impressions contained within a single sedimentary layer. Once the impression was made, the area remained undisturbed until another layer of sediment was deposited over the top, protecting the impression. Such impressions are among the most numerous of fossils, and they were the first recognized evidence of dinosaurs in the western hemisphere. Fossil hominid tracks have been found in Tanzania, and these tracks preserve some of the earliest life data for *Australopithecus*. The tracks were made over 3.5 million years ago and seem to represent a family unit, of father, mother, and child, walking together, with the child following the adults.

Original Preservation

Organic remains may be preserved unaltered in several ways. The common element for original preservation is extremely unusual circumstances. The cycling of organics from previously living plants and animals as part of their diet, then in turn their organics repeating the process, is responsible for supporting the variety and diversity of life on Earth today. Many mechanisms exist to perform the breakdown, and it is extremely unusual for any remains to escape all these breakdown processes. Encasement and desiccation are two processes through which unaltered remains may survive.

Encasement is a term reserved for preservation in an airtight medium such as tar, ice, amber, or copal. Organic remains preserved in this manner generally exhibit a certain amount of decay often leading to carbonization. However, freeze-dried mummies of Woolly Mammoths and a 5,000 year-old male human, a woman thrown into an asphalt pool at what is now Rancho La Brea, and mosquitoes from Dominican Republic amber (made popular in a major motion picture) are all exceptions. Each of these specimens has provided scientists with valuable clues from these exceptionally well-preserved remains.

Desiccation was one of the earliest observed preservation phenomena. Perhaps due to observations of animal and human carcasses that had perished in the desert, this same process has long been used by humans for the preservation of bodies. Egyptian mummies

were, in earliest times, created by being buried in the hot desert sand. However, as time went by, more and more procedures were added, and so in more recent times, desiccation was a minor factor in the total process.

Regardless of the means by which the fossil is preserved, original preservation retains the greatest amount of usable data for any specimen. However, much information has been gleaned from permineralized specimens, and even from natural molds and castings. Fossils provide a valuable resource for understanding life in the past.

FOUCAULT, MICHEL (1926–1984)

Foucault's university education was a mixture of philosophy and psychology. He combined this with strong interests in aesthetics, social history, and the history of culture and discourse to produce a rich body of work, which evolved through a number of stages, covering many issues and having an enormous influence across disciplines. His work is present in philosophy, cultural studies, art history, literary studies, and everywhere in the humanities, as well as the social sciences. His work is hard to define as a whole; he wished to challenge boundaries in thoughts. The title of his last academic post, Chair in the History of Systems of Thought at the Collège de France, clearly cuts across the disciplines.

Foucault's first really influential work was *Madness and Civilisation*, which looks like empirical social

science but also contains his other constants of an implicit engagement with the philosophy of Immanuel Kant, G. W. F. Hegel, Friedrich Nietzsche, and Martin Heidegger; an implicit engagement with the classics of social theory; and a commitment to the aesthetic expression of reality. He argued that there was a major shift from a premodern to a modern view of madness, in which the modern view was not an obvious improvement. The premodern view gave some of truth to madness, allowing it to confront the sane in the open. The modern view of madness rested on the institutional confinement, "the great confinement" of the "mad," who were now defined clinically instead of with reference to the possible insights of those who stand aside from apparent rationality. The premodern world defined the mad as other and separated them from the sane, just as the modern world did, but the consequence was not to hide them or to deny the value of all they said.

Through many shifts in Foucault's work, a position emerges that always remains. Social distinctions and discourse are inseparable. What we call knowledge rests on that interweaving. Power is inseparable from the way our social reality is created. Institutions can be understood only as expressions of this unity of power, knowledge, discourse, and social distinctions. Institutions can be studied as paradigms of that unity. There is a break between the modern and premodern periods, with a possible transition in the "Classical Age" (the French 17th century) and the Enlightenment. The modern period claims to be more humane than the premodern period but is not necessarily the case. The premodern period has manifest systems of separating and controlling what is "other" to normality; the modern period hides others and denies them any voice. The premodern period is aesthetic and openly agonistic; the modern period is rational and conceals conflict behind apparent the normality of universal values. Individual consciousness should be defined in terms of social structures and constraints, including those imbedded in our values and discourse.

Madness and Civilisation belongs to an "archaeological" period in Foucault's thought, where madness, hospitals, knowledge, and discourse are studied in terms of conceptual oppositions and discourse abstracted from everyday reality. A later stage of power/knowledge and the disciplinary can be established with reference to *Discipline and Punish* (1975). As in *Madness and Civilisation*, Foucault contrasted

the premodern and modern periods with reference to institutions, social relations, discourse, and power. However, he now emphasized that power and knowledge were inseparable and their point of union was in violence on the body. Power/knowledge exists not in terms of abstract theory or the legal sovereignty of the state, but in the networks of power that coerce the body. Power/knowledge exists in a dispersed way in local tactics of physical force, which precedes any discussion of beliefs and consciousness.

Foucault associates the premodern world with power, which exists as spectacular punishments. He begins the book with a notoriously distressing account of the truly spectacular cruel torture and execution of the would-be regicide Damians, in 18th-century France. For Foucault, that execution marked the end of the Ancien Régime in the broadest sense, as it marked the end of a whole history of spectacular punishment. Foucault challenges the idea that spectacular punishment was less humane than modern disciplinary punishment, where we are placed under observation in prison. Spectacular punishment offers the opportunity for the victim and the crowd to resist the sovereignty of power that guides the drama of execution. The discipline of the modern era turns the prisoner into a normalized passive individual, produced by supposedly humane practices such as prison psychiatry, which are in reality just another violence on the body. For Foucault, the prison is the paradigm of the modern institution: factory, school, hospital, army. There is a very specific paradigm offered of Jeremy Bentham's "panopticon." Bentham's design for a perfect prison is one in which cells are arranged around a central observation tower so that all prisoners can be observed but none of them know at which moments they are under observation. In the panopticon, everyone is potentially under constant surveillance and disciplinary control. Before the full emergence of this paradigm, Foucault sees it as anticipated in early modern "cameralist" theory, which defines state functions as branches of the police.

The next main phase of Foucault's thought concentrates on the aesthetic and ethical aspects of the body and individual autonomy. The three-volume *History of Sexuality* (1976–) is the most systematic product of that final phase, interrupted by Foucault's death. Here Foucault offers a classical model of self-perfection, defined through the erotic, as a guiding

principle. He denies the existence of sex or sexual categories such as "homosexual," the status of trans-historical truths. What we now call "sex" was known as "the flesh"; "homosexual" is a recently invented word with no direct earlier equivalents. Sexuality arises in various ways in which pleasure is enhanced through the frustration of pleasure. Repression produces pleasure, there is no pleasure without frustration, and the history of sexuality is the history of different ways in which this happens. We should avoid the assumption that any one age is more "liberated" or "repressed" than any other. The *History of Sexuality* suggests an aesthetic ethic of hedonistic-libertarianism, but only on the condition of forms of self-discipline and self-perfection. These claims should be compared with the lectures he gave at the *Collège de France*, where he moves away from defining the modern era as purely disciplinary on the cameralist model. He distinguishes between a modern approach of state control and the tradition of political economy and civil society. In the latter tradition, the state can successfully limit itself to enable individual and economic freedom.

Foucault seems to evolve from an earlier sympathy for Marxism to a later sympathy for Classical Liberalism. However, deducing consistent political conclusions from Foucault's work is notoriously difficult. What is consistent is a strong libertarianism in which Foucault analyzes the sovereignty of power and discourse, while trying to find forms of autonomy that can successfully resist them. This was also a personal commitment for Foucault, who campaigned for the rights of prisoners, psychiatric patients, and gays (he was an out gay himself who died as the result of AIDS, while still working on *The History of Sexuality*).

FRAZER, SIR JAMES (1854–1941)

Sir James George Frazer was born in Glasgow, in 1854; he died in 1941 in Cambridge, where he spent most of his academic life. He was the best-known anthropologist of his time. His work was deeply influenced by Auguste Comte, Herbert Spencer, and E. B. Tylor; that is to say, he applied a comparative and evolutionist approach to all available data, old and new. His solid foundation in the classics provided much of his comparative material. His main work, *The Golden Bough*, appeared in several editions: the first one in 1890, the last, abbreviated one, in 1922. It is still in print. This work, a comparative study of the evolution of religion as well as his many other publications on a variety of topics, influenced anthropologists, classicists, folklorists, scholars in the humanities, and psychologists, as well as the general educated reader, to whom most of his works are addressed. He was elected member of the British Academy in 1902 and was knighted in 1914.

Frazer, trained as a classicist and lawyer, first wrote on classical topics: the Roman historian Sallust (1884) and a six-volume edition on the 2nd century CE Greek antiquarian Pausanias (1898). This guidebook, the *Description of Hellas*, lists objects worthy of visiting in Greece, adding legends, stories, and anecdotes about them. Pausanias lists “survivals” of earlier times, a phenomenon that had been extensively documented by Tylor in his *Primitive Culture* (1871). Both works greatly influenced Frazer, whose methods were slow and meticulous: For instance, the work on Pausanias may have begun in 1884 but only reached publication 14 years later, in 6 volumes, totaling 3,000 pages.

In that same year (1884), Frazer met W. Robertson Smith, a fellow Scotsman who had been hired by Cambridge after having been run out of the Free Church College at Aberdeen in 1881 because of his heretical views. Robertson Smith was an ordained minister and worked on biblical subjects; he was the (future) author of *Lectures on the Religion of the Semites* (1889). However, at that time, he worked as an editor for the 9th edition of the *Encyclopedia Britannica*. He invited Frazer to submit some articles, all on the letter “P” and beyond. Frazer wrote the entries for Penates, Priapus, Proserpina, Pericles, Taboo, and Totem. Especially the latter two topics pushed him further into the direction of anthropology,

Source: © Bettmann/CORBIS.

and in 1887, he created a list of questions for those going into the field: *Questions on the Manners, Customs, Religion, Superstitions, etc., of the Uncivilized or Semi-Civilized Peoples*. The purpose was for others to collect the data in a systematic manner everywhere, so that true comparatists (like Frazer himself) could analyze the whole, preferably from their armchairs.

Frazer's subsequent major work, *The Golden Bough* (first ed. 1890, 2 vols.), carried the subtitle: *A Study in Comparative Religion*. Its main topic was the Aryan myth of the dying king or priest, whose death reinvigorates life on earth. He supported his thesis with multiple anecdotes, both ancient and modern. He argued that survivals of primitive religion(s), the result of diffusion, could still be found among farmers and other backward populations in Europe and could also be detected in some religious practices current in Christianity. His Victorian readers were alarmed to see such festivals as the Roman Saturnalia, the Crucifixion of Christ, and Purim linked as rites of renewal. Frazer's opinions on religion, especially Christianity, were expressed most strongly in his first edition of *The Golden Bough* but were gradually

toned down or drowned in comparative detail. The thrust of his work, however, remained the same.

The second edition (1900, 3 vols.) carried the subtitle: *A Study in Magic and Religion*. It highlighted the inability of the “savage” to understand the difference between the natural and the supernatural. As civilizations matured, magic was replaced by religion, which in its turn was shown to make room for science. *The Golden Bough* grew to 13 volumes (1918) and was edited down to a single volume of 800 pages (1922). A supplement, *Aftermath*, appeared in 1936, 5 years after Frazer had gone blind and relied on the help of assistants. Frazer’s constant need for money—and the flood of new information coming in from Australia courtesy of W. B. Spencer and F. J. Gillen—drove him to revise many of his works, bringing in a stream of steady advances from his friend and publisher, George MacMillan.

Later in life, Frazer returned to work in classics, publishing a translation and commentary of *The Library*, a collection of Greek myths attributed to Apollodorus (mid-2nd-century BCE) in 1921. He published a translation of Ovid’s *Fasti* (1929), a compendium in verse of Roman beliefs and customs related to the calendar. As his reputation among professional anthropologists waned, it increased among the general public. He wrote the introduction to Malinowski’s *Argonauts of the Pacific* (1922); Freud wrote his *Totem und Tabu* (1913), inspired by Frazer’s *Totemism and Exogamy* (4 vols., 1910). Frazer also influenced the so-called Cambridge ritualists (Jane Harrison, Francis Cornford, Gilbert Murray, A. B. Cook), a group of classical scholars who believed that ancient Greek religion and myth provided the clue to the origins of tragedy.

FREEMAN, DEREK (1916–2001)

John Derek Freeman was born in Wellington, New Zealand. He first studied anthropology when Ernest Beaglehole offered a course on the subject through the Psychology Department of what is now Victoria University of Wellington. In 1940, Freeman took up a position teaching in Samoa, where he remained until 1943. Freeman subsequently studied at both University College London (MA Phil., 1948) and Cambridge University (PhD, 1953), writing a master’s thesis on Samoan social structure and a doctoral dissertation on the Iban of Sarawak, Borneo. This latter work grew out of Freeman’s 1949 to 1951 field study of the Iban. Freeman returned to New Zealand, teaching briefly at the University of Otago in Dunedin, before taking a position at the Australian National University in Canberra in 1957, where he remained until his death.

Thus, while he must have read some American or Boasian four-field anthropology, notably the work of Margaret Mead on Samoa, Freeman was largely trained in and taught within the British tradition of social anthropology.

Despite the quality of Freeman’s Iban work, he was best known for his role in the so-called Mead-Freeman debate. For Freeman, this debate, at heart, concerned evolution. Freeman had become interested in the subject in the mid-1960s, not long before he returned to Samoa to undertake fieldwork. His later, more developed, position held that humanity’s evolutionary history had produced a creature capable of making choices but nonetheless one whose capacities for responding to the world were embedded in biology, hence derived from the evolutionary past. Freeman considered that most modern anthropology had abandoned a concern with evolution and with human biology. He understood his part of the debate as both an exploration of anthropology’s history and a correction of anthropological theory.

Freeman’s first major statement in the debate was his 1983 volume, *Margaret Mead and Samoa: The Making of an Anthropological Myth*. The book is organized into two broad sections.

The first section advanced a historical argument. According to Freeman, Mead’s teacher, Franz Boas, had become alarmed at the rise of the eugenics movement within the generally racist societies of the

United States and Britain. Accordingly, Boas had encouraged his students to gather materials that tended to emphasize the variability of human beings and thereby call into question the notion of an underlying, universal human nature. One of Boas's nemeses, G. Stanley Hall of Clark University, published a major work arguing that adolescence is everywhere a time of so-called storm and stress. As part of Boas's general project, Margaret Mead went to Samoa in 1925, intent upon studying female adolescence. In her 1928 book, *Coming of Age in Samoa*, Mead concluded that the young women and the girls she studied, all things considered, led comparatively stress-free lives.

Mead's argument attained wide circulation when her publisher, William Morrow, insisted that Mead add two chapters of material comparing Samoan and American adolescence. More important, for Freeman, modern anthropologists, unaware of or indifferent to the shortcomings of Mead's analysis, would contend that her Samoan findings supported radically culturalist hypotheses, emphasizing the mutability of humanity over and against more biologically grounded theories of an evolving human nature.

In the second section, Freeman undertook what he insisted was a Popperian refutation of Mead's thesis rather than an ethnographic report per se. Freeman presented a range of materials designed to show that Samoa was considerably more violent than Mead allowed and that female chastity prior to marriage was highly prized. Under the traditional system, some daughters of high-ranking men, identified as *taupou*, had been publicly deflowered by members of the groom's family as part of their wedding ceremonies. While Christian missionaries had inveighed against the *taupou* system, their influence contributed to a subsequent general prudishness. Freeman mentioned briefly that most Samoan women eloped (*avaga*), asserting that such elopements established the women's previous virginity.

Beginning with this assertion about female premarital chastity, much of the debate came to be focused around Mead's accounts of Samoan female adolescent sexuality, especially the inference that adolescents undertook perhaps multiple casual affairs. Much of Mead's description of Samoan female adolescence receded into the background; for Mead, these young women were generally junior, socially minor members of a highly stratified society, in which not only did they have little of importance to do but also

their daily activities were often of little interest to their social superiors. During his second period working in Samoa, Freeman was an older, married man. He had been given chiefly titles by his chiefly interlocutors. He likely would not have had easy access to young women, as Mead clearly did.

Freeman, in his second book, contended that a young and relatively inexperienced Mead had been attempting to undertake two unrelated projects at once: one on female adolescence and the other on Samoan social organization. Rather than having made up her results, he claimed, Mead had more simply fallen victim of a hoax. Two of her informants, Fa'apua'a Fa'amā and Fafao, while accompanying Mead on a trip had become embarrassed by Mead's questions. In a fashion well understood by Samoans, they told Mead what they thought she wanted to hear: They had lovers when, in fact, they did not. According to Freeman, Mead, having gathered her only explicit statements from young Samoans about their sexual experiences, then wrote Boas, claiming to have gathered information supportive of culturalist arguments.

Freeman's supporting evidence was of two sorts: a filmed statement by an elderly Fa'apua'a Fa'amā, stating she had hoaxed Mead, and a range of documentary sources, including Mead's papers. Freeman's use of both of these sorts of evidences has been criticized.

Some have contended that Fa'apua'a Fa'amā may have been hoaxing Freeman or, more important, that she may not have been and likely was not, given Mead's text, Mead's sole source.

More concretely, Freeman's chronology of Mead's fieldwork was not wholly convincing, his arguments were anachronistic, and his use of documentary evidences faulty. He neglected the continuing presence of biological or physical anthropology within the Boasian conception of anthropology's four fields. Aside from his references to eugenics in his first book, he did not discuss the biology of the pertinent era when Boas and the young Margaret Mead had engaged in the activities he criticizes; rather, Freeman spoke from a perspective defined by the biological understandings of the later 20th century. He largely ignored Mead's use of the concept of "temperament," the interest Boasians such as Goldenweiser had in biological ideas such as convergent evolution, as well as the relationship between Benedict's notion of cultural selection and Darwin's idea of sexual selection. He repeatedly took quotes out of context, in some

cases clearly misrepresenting the apparent or plain meaning of the text quoted.

FRENCH STRUCTURALISM

Structuralism is a powerful theoretical framework that dominated French thought in the 1960s. Deriving from the insights of the Swiss Linguist Ferdinand de Saussure and receiving its most comprehensive expression in the anthropology of Claude Lévi-Strauss, the structuralist paradigm also operates in the political philosophy of Louis Althusser, the psychoanalysis of Jacques Lacan, the “narratology” of Roland Barthes, the sociology of Pierre Bourdieu, the “history” of Michel Foucault, and the genre studies of Tzvetan Todorov.

Uniting a generation of intellectuals against the postwar hegemony of Sartre’s existentialism, with its emphases on the individual will and the act but also defined against phenomenologists such as Merleau-Ponty, structuralists were interested in the ways that acts were constructed by forces beyond individual consciousness. Structuralists saw systematic patterning in human expressions and actions that indicated not individual free will, but rather, structures of language, power, culture, and the psyche that had more or less determinant influences on consciousness.

Saussure’s Premises

Before Saussure, the field of linguistics had primarily consisted of cataloguing the world’s languages and tracing etymologies. Saussure rejected the study of

empirically available elements of language for the study of the independent formal relations between them. In his *Cours de Linguistique Générale*, delivered as a series of lectures in Paris in the first decade of the 20th century, but only edited after his death, Saussure put forward several propositions about language that are definitive for the later development of structuralism. He postulated that language was a coherent social system regulated by the principles of syntax and semantics and that the structure of language consisted in the relations (principally oppositions) between its elements.

He further maintained that any given “signifier” (word) stood in a purely conventional relationship to its “signified” (meaning), with nothing essential, intrinsic, or even stable about the association. To understand language, therefore, linguists needed to chart the logical relations governing the production of utterances rather than these surface forms themselves: grammar rather than speech or, in Saussure’s terms, *langue* rather than *parole*.

A Russian disciple, Troubetzkoy, achieved great success in applying Saussure’s postulates to phonology. Troubetzkoy’s student Jakobson, founder of the Prague Linguistic Circle, who would be Lévi-Strauss’s colleague at the New School before and during the Second World War, developed Saussure’s science of signs to analyze poetics.

Structuralist thought holds other social systems to be analogous to language, as defined by Saussure. Just as language grammars, of which most speakers are not consciously aware, govern the production of utterances, cultural, political, and other social phenomena conform to grammars or codes. Furthermore, Lévi-Strauss and Jakobson shared with psychologist Jean Piaget and Biologist François Jacob a conviction that a genetic mechanism acts as a “structuring force” in man.

Structuralist Anthropology

Lévi-Strauss saw cultural variation as a difference of number and arrangement, like, to use a favorite analogy, various melodies composed from a determinate number of keys. He studied the variations to generate the laws of transformation that formed the essential cultural grammar and indicated universal innate structures of mind. The ultimate goal was *l’attitude totalisante*, the awareness of complex social structure as determined by “unconscious reason.”

Confusingly for the student of the history of anthropology, English social anthropology had already been describing its approach as “structural” or “structural functional.” Radcliffe-Brown developed this other “structural anthropology” using Malinowski’s concepts of functionalism. For Malinowski, human societies were the analogs of biological organisms, and institutions were explained by their contributions to social homeostasis, just as the organs of the body were explained by their regulatory or therapeutic functions. For Radcliffe-Brown, “structure” was equivalent to social organization. The network of “actually existing” social relations formed a society’s structure, and consistent with the natural science paradigm, their quality was intrinsic to this structure.

For Lévi-Strauss, however, structure was the code governing the form of social institutions rather than anything that was itself empirically available. His analysis would focus on the quality of the relationships between the elements of his object of study and their arrangement.

Both Lévi-Strauss and Radcliffe-Brown wrote about the pronounced cross-cultural variations in the quality of the relationship between a son and his mother’s brother. Radcliffe-Brown took the “elementary family” consisting of “a man and his wife and their child or children” to be the basic unit of kinship. The relationships among the members of this family were first-order kinship relations, and those connecting family units were second-order relations. Lévi-Strauss believed this to be a fundamental misunderstanding.

For Lévi-Strauss, the biological family was a term of the second order. The essential function of kinship was not the individual reproduction performed by the elementary family, but the establishment of relations between elementary families. Only by taking as the basic unit of kinship a configuration, including two pairs of correlative oppositions and each of the three types of familial relation (consanguinity, affinity, and descent) in each generation, does one have a meaningful structural unit, the building block of elaborate kinship systems. That is, it is only by drawing the relations between the pairs—brother/sister, husband/wife, father/son, mother’s brother/sister’s son—that the incest taboo, and the avunculate as its corollary, can be explained.

Lévi-Strauss generated a model capable of expressing the apparently contradictory forms of behavior across cultures—a deep structure of avunculate expressions. Comparing the Trobriand Islanders and

the Cherkess of the Caucasus, he found that “in both groups, the relation between the maternal uncle and nephew is to the relation between brother and sister as the relation between father and son is to that between husband and wife. Thus if we know one pair of relations then it is always possible to infer the other.”

In taking the biological family as the basic unit, Radcliffe-Brown had taken an arbitrary system of representation for objective ties of consanguinity and descent between individuals. “Any concession to naturalism might jeopardize the immense progress already made in linguistics, which is also beginning to characterize the study of family structure, and might drive the sociology of the family toward a sterile empiricism, devoid of inspiration.”

In the introduction to *The Raw and the Cooked*, Lévi-Strauss maintained that myth was a fundamental object of study for the structural program, because, unlike kinship, it was not directly tied to a different order of reality. In myth, “the mind imitates itself as object.” For Lévi-Strauss, myths function as mediating structures. As the spatial, formal, or material dichotomies figuring in the narrative of a given myth (high/low, water/earth, raw/cooked, sun/moon) relate symbolically to the basic problems confronting the human mind (male/female, life/death, nature/culture), myths perform vital intellectual and cultural tasks. Myths symbolically resolve, rearrange, decide, or explain by playing with binary oppositions.

The *meaning* of a myth resides in the way the narrative elements are combined. It is only the relations between elements that transmit information, express beliefs, ritually explain behavior patterns, and mediate the paradoxes created by social life. For example, in the series of myths whose analysis comprises *The Raw and the Cooked*, the logical relations between the qualities of “rawness” and “cookedness” that appear in the narrative differentially express beliefs and behaviors surrounding the antagonism between nature and culture. The extension of these terms—raw→moldy and cooked→burnt—represents one of the ways binary oppositions can be mediated and resolved.

The codes governing the production of myths are distinguished by comparing variants of the same myth along different conceptual axes, such as in Lévi-Strauss’s analysis of variants of the Oedipus myth in *Structural Anthropology*. Myth’s basic element is more complex than that of linguistic production. The “mytheme” (“Cadmos kills a dragon,” “Oedipus kills

his father,” or “Oedipus marries his mother”) stands in relation to the seme or word as that element does to the morpheme or indivisible phonological unit. To the dimensions of language—*langue* and *parole*—the mythic code adds a third time-out-of-history level of operation.

Lévi-Strauss has been criticized for abstracting symbols out of their sociocultural contexts—denying the meaning-giving operations of specific historic, cultural, and personal conjunctures. However, he considers rigorous ethnographic methods necessary to the semantic level of his project. In analyzing individual myths, he relates narrative elements to the concrete social organizations, ritual practices, subsistence techniques, and basic geographies of the societies to which they belong. He uses ethnographic data to draw out the mediating functions of the opposing terms in the collected narratives. Lane proposes, in Lévi-Strauss’s defense, that the structural method achieves a synthesis between the thesis—general properties of social life—and the antithesis—particulars of social anthropology.

Additional Influences

Lévi-Strauss credits Marx, Freud, and geography with the inspiration for his method. Elaborating on Marx’s understanding of the relationship between a society’s material economic base and its social and ideological superstructure, Lévi-Strauss describes the myth as an epiphenomenon of concrete social fact. His analyses also depend heavily on Freud’s notions of unconscious psychic operations and particularly the operations by which symbols are created and invested. With Freud, he reads the “reason of the unconscious” in the creation and operation of these epiphenomena. He credits geology with the methodological proposition of simultaneous synchronic and diachronic readings. Just as one needs both to survey a landscape and to excavate at a certain spot to reach a geological understanding, to understand a mythical structure, one needs to “excavate” the meaning at a particular juncture as well as reading along the irreversible temporal axis.

Also important as intellectual forbears of the structuralism of Lévi-Strauss are Swiss anthropologist Émile Durkheim and his son-in-law, Marcel Mauss. Durkheim identified cultural forms as collectively authored and susceptible to symbolic readings as fulfillments of basic social needs. He also saw basic

homologies between social institutions and categories of thought, although he tended to read from the social to the individual, or in the opposite direction from Lévi-Strauss. Lévi-Strauss himself credits Mauss’s *Essai sur le don* with the first example “in the history of ethnological thought” of “an effort to transcend empirical observation and to achieve a deeper reality” (Lane, 1970, p. 30).

Structuralism’s Prehistory

Marx is a significant precursor for the work of many French structuralist social scientists, notably Althusser, Bourdieu, and Foucault. Marx provided a framework for understanding why the actions of individuals would ultimately conform to their structural class interests, but he also proposed that acts could transform the structures of social relations of production. Lévi-Strauss forsook Marx’s dialectical historicism for a determinant structure—the innate capacities of the human mind—that existed outside of historical time and was not susceptible to dialectic change. Others returned to Marx’s social analysis but frequently concentrated on the determinant force of social structures on consciousness to the neglect of the effects of consciousness on history.

Lévi-Strauss’s philosophy, although widely admired for its intellectual force and its elegant expression, found only a few committed adherents in England and America. Foremost among his British followers is Edmund Leach, and David Schneider is perhaps the best-known American structuralist. The American response has primarily been a reassertion of the significance of individual consciousness, location, and “voice,” informed particularly by the increasing awareness that the societies studied by anthropologists are characterized by internal conflict and differential access to power. Structuralism’s synchronic approach was also distasteful to postcolonial critiques and their insistence that the societies studied by anthropologists be placed in specific moments in global history.

Deconstructionism and Poststructuralism

Ironically, the “deconstructionist” and “poststructuralist” movements that followed the structuralist ascendancy in Paris derive equally from Saussure’s insights into the operation of language and include

some of the same figures—notably Barthes and Foucault—claimed by structuralism. Derrida, in particular, developed the Saussurian premise that meaning existed only in difference. But this intellectual generation, sometimes dated to the uprising of May 1968, forsook any belief in a stable code. In fact, for them, belief in the fixity of signification has politically suspect motivations.

FREUD, SIGMUND (1856–1939)

Sigmund Freud, born in Freiberg, Moravia, on May 6, 1856, and now known as one of the greatest minds of the 20th century, was a physiologist, medical doctor, psychologist, and the father of psychoanalysis. He postulated that many neuroses (mostly phobias, hysteria, chronic pain, and sometimes forms of paranoia) had origins in past traumatic experiences that were forgotten or hidden in the unconsciousness. Discoveries such as this made Freud one of the most provocative thinkers of his time.

Although Freud was an extremely influential thinker, his pioneering thoughts were set in motion by the works of other influential thinkers that preceded him. Two in particular are Charles Darwin, a naturalist, and Freud's early mentor Ernst Brucke, under whom Freud studied physiology while enrolled in medical school at the University of Vienna. Darwin

revolutionized the conception of mankind when he published *The Origin of Species* in 1859. Up to that time, the human species was viewed as being distinct from the animal kingdom. However, Darwin theorized that not only is our species a part of the animal kingdom but it has also changed physically over time, just as all members of the animal kingdom have. This concept, known as *evolution*, suggested that mankind could be viewed as an object that can be investigated scientifically. Freud, first and foremost a scientist, accepted this idea implicitly and examined the human psyche analytically and scientifically.

The second groundbreaking concept that allowed Freud to develop his own original thought was work done by Freud's teacher Ernst Brucke. Brucke published work stating that all living organisms (including our species) are, like inanimate objects, energy systems, which are subject to the laws of thermodynamics, in particular the principle of conservation. The principle of conservation as formulated by physicists Mayer, Joule, and later Helmholtz states that "energy is neither created nor destroyed, rather it only changes form." Brucke's application of this law of conservation to living systems was called *dynamic physiology*. Freud adopted dynamic physiology with enthusiasm, and it was only a short time before he conceptualized that such a thing as *psychic energy* existed and that the human personality was also an energy system. This concept would form the cornerstone of his psychoanalytic theory.

Two fundamental concepts developed by Freud are the *reality principle* and the *pleasure principle*. The pleasure principle, in a basic sense, tells the organism to do whatever feels good or whatever brings pleasure, such as satiating hunger or thirst or avoiding painful stimuli. However, the organism is particular in the sense that it acts to survive and to reproduce. Therefore, the urge to have sex is a powerful motivating force behind an organism's behavior. In addition, because the organism is a closed system and is dependent on the external environment that it experiences, it must be mindful of laws and rules involved with interacting with this environment. The reality principle tells the organism to subordinate pleasure to what is necessary, that is, procuring adequate food, work, and shelter, and so on.

In the human psyche, the conflict that arises between the pleasure principle and the reality principle is internalized by three properties explained by Freud, the *id*, the *ego*, and the *superego*. The inherited

Source: © CORBIS.

id operates in keeping with the pleasure principle, that is, the demand to take care of needs and, to an extent, instincts. Freud defined the translation of needs to wishes, provided by the pleasure-seeking id, as the *primary process*.

The ego is what relates man to reality by what Freud calls its *consciousness*. The ego functions in accordance to the reality principle. The problem-solving behavior that the ego uses to attain desired objects is known as the *secondary process*.

The ego struggles to satisfy the id but keeps track of the obstacles and strategies used to obtain its objects and the rewards and punishments encountered. This record of strategies and things to avoid becomes the superego, which also represents external society and its cultural restraints. According to Freud, the superego has two components, the *conscience*, which is an internalization of punishments and warnings, and the *ego ideal*, which is derived from rewards and positive models. In addition, the conscience and ego ideal relay their requirements to the ego with such feelings as pride, shame, and guilt.

According to Freud, the morals and ethics of a society may force an individual to repress desires and wishes presented by the id. Freud proposed a defense developed to cope with this dilemma and called it *sublimation*. He proposed that sublimation is the transformation of what society deems unacceptable impulses, such as sex or anger, into a socially acceptable form. An individual with a great deal of hostility may become a football player or a hunter. Someone with immense sexual desires may become an artist or a musician. Freud proposed that all creative activities were sublimations and were inherently motivated by the sex drive. (Freud called sexual energy the *libido*.)

Freud also believed that from the moment an infant is born, it is driven by the id to desire bodily pleasure. This is known as *infantile sexuality*. As a result of infantile sexuality, Freud proposed, early childhood sexual experiences were the crucial factors that influenced the development of the adult personality. He described five psychosexual stages in this process of development. The first stage is called the *oral stage*, which lasts from birth to 18 months. During this stage the focus of pleasure involves the mouth. The infant satisfies this desire by sucking and biting. The second stage is the *anal stage* and lasts from 18 months to 3 or 4 years of age. During this stage, the focus of pleasure is the anus and the act of holding in and letting go of feces. The third stage is the *phallic stage*, which lasts from ages 3 to 7. In this stage the focus of pleasure is the genitalia, and masturbation is common. The fourth stage is the *latent stage*, which lasts until puberty. During this stage, sexual urges are suppressed in favor of learning. The fifth stage is the *genital stage*, which begins at puberty. Freud believed that the resurgence of the sex drive occurs in this stage. During this stage, the focus is the pleasures of sexual intercourse.

During a child's development, Freud concluded, an *Oedipus/Electra complex* takes place. This complex is based on the psychology that a child's first love is the mother and that the child desires physical contact with her (this satisfies the id). A male child realizes that the father, the bigger, stronger male, gets the mother's love too and gets to sleep in the same bed with her. This eventually causes the male child to view the father as a threat, and this constitutes the Oedipus complex. With a female child, it becomes evident that there is a difference between boys and girls, that is, that boys have a penis and girls do not. It is also realized that the father has one, which is

why his relationship with the mother is different, and that the female child will never be able to have that (this is known in Freudian terminology as *penis envy*). So the female child's first love is the mother, but with all differences taken into consideration, she turns her attention toward the father and views the mother as a threat for his attention; this is the Electra complex.

The Oedipus and Electra complexes, according to Freud, may also influence sexual preference and bisexuality. He justified this theory with his fundamental concept of the id and the superego and believed that this was the time in which children begin (via the superego) to repress their attraction for one sex and develop an attraction for the other (usually the opposite). However, some children do not do so and instead develop attractions for the same sex or for both sexes. Freud also postulated that homosexuality and bisexuality were based in *narcissism*; however, he was never completely satisfied with his definition of homosexuality and bisexuality in respect to the human psyche.

Freud believed that an *unconscious mind* existed and based this idea on his belief that different mental states must exist. Freud pointed out that certain neurotic or compulsive behaviors could not be accounted for by the actions of the conscious mind. Therefore, an unconscious mental process must exist, which is hidden from consciousness. For Freud, instincts were rooted in the unconsciousness and were the principle motivating forces in the mental realm. He grouped instincts into two main categories: the *eros* (the life instinct) and the *thanatos* (the death instinct). Eros comprises the self-preserving and erotic instincts, whereas thanatos is geared toward aggression and self-destruction. Eros is motivated by the id and the sex drive. Thanatos is not motivated by the sex drive and is an irrational urge to destroy the self. According to Freud it was the root of suicidal urges in some of his patients. However, Freud also believed that the urge to commit suicide could not exist without a previously repressed urge to kill someone else.

Believing that an unconscious mind must exist, Freud went on to develop the *psychoanalytical method*, which in general terms was a method of reestablishing a harmonious relationship among the id, the ego, and the superego and of resolving any unconsciously repressed conflict. He developed this *talking cure* and encouraged his patients to relax by lying down on a couch. Then he reduced the amount of stimuli, even

putting himself out of sight during the session. This method allowed his patients to discuss their problems freely and to relinquish the repression of the superego, allowing Freud to close in on the root of the problem. He also emphasized dreams and symbolism. He believed they were important because, during sleep, the superego is not able to repress the desires of the id and the feelings in the unconscious.

Today, many of Freud's ideas are still a predominant force in psychoanalysis, although some psychoanalysts disagree and disregard some of his ideas. However, what Freud accomplished in his day and age must be acknowledged. His pioneering ideas and vision have in fact made it possible for modern thinkers to attempt to disprove his ideas. He will always be remembered as one of the first to brazenly delve into the unconscious human mind, grasp its fundamental meaning, and then attempt to explain it to the people of his time.

NEO-FREUDIANISM

Neo-Freudianism is a system of psychoanalysis based on Freudian doctrine, but modified by emphasizing social factors, interpersonal relationships, and other cultural influences on personality development or as causes of mental symptoms or diseases.

In the 1950s, some anthropologists called for a return to Freud, attempting to use his basic

insights into the relationship between culture and personality. However, they avoided some of his excesses and oversimplifications. Neo-Freudianism also pays attention to function rather than considering culture to be a projection of inner states. It considers social roles, too.

Later psychologists often believed in the underlying structure of Freudianism, but thought it was too narrow and stringent. Erik Erikson was one of the most prominent Neo-Freudians. He was a child psychologist and had trained with Sigmund Freud's daughter. He expanded upon Freud's theories, attributing greater status and autonomy to the ego, and considering it independent of the id in function and origin. He also put less emphasis on the psychosexual instinct and its influence on determining personality. Instead, he emphasized psychosocial development.

Freud's theories are all based on adult psychoanalysis. Erikson and others also included studies of infants and children. He believed parents' behavior was less important in shaping personality than Freud had thought.

August Aichorn, author of *Wayward Youth*, was one of the first Neo-Freudians to apply his theories to the psychoanalytic explanation of crime. He believed that an underdeveloped superego rather than an overdeveloped superego was the primary cause of crime. He popularized the notion that delinquents need unconditional love, rather than being institutionalized in a punitive setting. He believed many people who committed crimes had grown up without loving parents.

Healy believed that delinquents most frequently used displacement as a defense mechanism. This behavior includes compensating, substituting, and ditching. He discovered this while working at his psychiatric clinic in Chicago. He believed 91% of delinquents were emotionally disturbed, half because of a broken home and the rest because they were given too much or too little parental discipline.

Erich Fromm is sometimes cited as a Neo-Freudian, but his theory is a blend of Freud and Karl Marx, with the idea of freedom added. He believed people had the ability to transcend determinisms Freud had attributed to them.

— Pat McCarthy

FRIED, MORTON H. (1923–1986)

The highly influential writings of American anthropologist Morton H. Fried have made key contributions to explaining the origins of the state and its attendant modes of social stratification. Fried devised an evolutionary framework to describe the basic processes that account for general similarities in independent sequences of cultural complexity. Asserting that all significant differences among modern and historical world societies can be regarded as distinct stages of cultural development, from simple to complex, Fried argued that political integration covaries with economic differentiation.

By focusing on the interplay of resources, wealth, power, and political authority in the context of redistribution and reciprocity, Fried argued that states emerge from an ordered succession of less complex social forms, including egalitarian, ranked, and stratified societies. Egalitarian societies are those in which status differentiation and political leadership are situational and based on personal achievement (within the limits of age and sex) under conditions of generally equal access to economic resources. Out of these groups emerge societies that employ ranking as a structural principle for integrating multiple communities along kinship lines. Ranking of individuals and lineages is based on primogeniture, in which rank is hierarchically related to descent from an apical ancestor (the “chief” is Elman Service’s typology).

According to Fried, stratified societies emerge from ranked groups that develop differential access to basic productive resources, such as land and water. Control and management of strategic resources provides opportunities for certain individuals to accumulate material wealth, which can be manipulated to generate social or political capital, for instance, by establishing reciprocal return obligations vis-à-vis contractual debt relationships. Fried believed that this social form is an ephemeral, fragile, and volatile condition that rapidly gives rise to complex political economies expressed as state developments or else breaks down into less complex socioeconomic forms. This is an important observation, because it acknowledges social devolution, in which complex societies decompose into less complex forms.

While many scholars have characterized Fried’s framework as a unilineal evolutionary typology, Fried recognized an important distinction between

“pristine” (or “primary”) and “secondary” developments. Pristine evolutionary developments refer to new levels of sociopolitical integration that emerge autochthonously in the absence of external influences from more complex societies. Secondary developments involve evolutionary changes that emerge as a result of intercultural interaction with more complex societies. Thus, Fried’s model is dendritic and accounts for cases that fall outside of unilineal models of progressive cultural evolution (band → tribe → chiefdom → state), such as those of Elman Service and Marshall Sahlins.

Despite the elegance and explanatory power of Fried’s model, a tremendous amount of variation in intermediate social formations has been documented with ethnological and archaeological evidence since Fried’s initial publications in the 1950s and 1960s. This growing body of information suggests that an emphasis on nomothetic processes and general unilineal evolution is inadequate for explaining variability in specific sequences of change in complex social systems. Instead, recent scholarship contends that variation must be explained by historically contingent circumstances, where unique cultural trajectories derive from, or are shaped by, local differences in social and natural landscapes.

FRIENDSHIPS

The concept of friendship refers to a social phenomenon that is characterized by a diversity of ties and connections to a variety of degrees that are shaped by complex sociocultural codes. As a configuration

of sociocultural practices, friendship remains an open concept used by researchers from different fields. Anthropologists, for example, experience their immersion in fieldwork through friendship. Personal relationships are central to the production of anthropologists’ ethnographic enterprises. This is illustrated by the figure of the “key informant” in anthropology, which constitutes a highly polysemic medium that translates the cultural codes being studied by the ethnographer into intelligible fragments of understandings, recorded in field notes and transcripts. The relationship between the informant and the ethnographer is also the main theater in which contradictory emotions and feelings related to “social and cultural encounters” are played out.

Friendship (and its antonym, enmity), although undertheorized by anthropologists, is at the core of the anthropological textual mediation for understanding of differences, power relations, hierarchies, and cultural practices. This is reflected in many ethnographic reports and essays on a wide array of contexts. These range from anthropologist-informant relationships to gender and sexuality (including erotic subjectivity in the field and the role of gender, family, and intimacy in structuring friendship during the practice of fieldwork) as well as role and allegiances of anthropologists in the community being studied. Other foci related to friendship include the importance of friendship networks in creating access for anthropologists, how circumstances of fieldwork shape political repositioning of anthropology as a discipline distinct or separate from its colonial heritage, in addition to providing an analytical space for understanding mechanisms of oppression and social suffering. As anthropological study mostly takes place in contexts in which power relations underlie structures of oppression, anthropologists witness in-depth diverse human experiences of vulnerability that, in turn, contribute to their sympathy for the vulnerable, which may drive their narratives to the mainstream of the discipline in less of an ethnocentric or colonial way.

The conceptualization of friendship as relevant subject matter to think about sociocultural life is a recent endeavor, but its impact in helping reevaluate classical anthropological descriptions and analysis of sociocultural situations in both non-Western and Western societies is far-reaching. For instance, categories such as kin-friend and “idiom of affinity” were introduced in order to stress, in the first case, the

Source: PhotoDisc/Royalty Free.

equal importance of both kinship and friendship in social life and, in the second case, an ideology that ultimately confirms and strengthens hierarchies between groups and individuals while reaffirming the affinity of their shared imaginary world. Effort to think about friendship as a relevant social phenomenon has led to its cross-cultural conceptualization in a way that can only enrich anthropological discourses. Comparative studies of friendship help revise its Western-centered content and recall many stereotypes that used to prevent researchers from thinking about differences along a continuum rather than merely in terms of the duality “us versus them.”

FROMM, ERICH (1900–1980)

Erich Fromm was born in Frankfurt, Germany, into an Orthodox Jewish family. A grandfather and two great grandfathers had been rabbis; an uncle was a Talmudic scholar.

Fromm studied at universities in Frankfurt and Munich before receiving his PhD in sociology from the University of Heidelberg in 1922. Though he lacked any formal medical training, Fromm soon began studying at the Psychoanalytic Institute in Berlin, under Hans Sachs and Theodor Reik. In 1926, he married Frieda Reichman, a psychoanalyst who later made important contributions to the study of schizophrenia. About this time, no doubt influenced by his studies and by the First War, Fromm abandoned

the practice of Judaism, though its influences would not be absent from his thought.

The Fromms moved to Frankfurt, where he was among the founders of the Frankfurt Psychoanalytic Institute. Max Horkheimer invited him to join the Institute for Social Research. During this period, Fromm worked on a study on the character structure of German workers, published posthumously as *The Working Class in Weimar Germany*. The Fromms divorced after 4 years of marriage.

Source: © International Erich Fromm Society.

In 1934, Fromm followed other members of the Frankfurt School to the New School of Social Research in New York. He would teach there, at Columbia, Yale, and Bennington, among other American institutions, until 1950. Early in this period, he was befriended by and came to influence Margaret Mead.

Fromm's first major book, *Escape From Freedom*, appeared in 1941. Showing the range of influences on Fromm's thought, its critique of the limits of Freudian psychobiology led to his expulsion from the New York Psychoanalytic Institute in 1944. Along with Harry Stack Sullivan and others, he then helped found the William Alanson White Institute; Fromm served as its clinical director from 1946 to 1950.

By then an American citizen, Fromm took up a post at the National Autonomous University in Mexico City. He taught there until 1965. He founded and until 1976 directed the Mexican Institute of Psychoanalysis but still remained active in American politics and intellectual life.

In 1976, Fromm, along with his third wife, moved from Mexico to Switzerland, where he later died.

Fromm's work was an extended meditation upon the social-psychological consequences of human existential separation. For Fromm, biological constraints, so important in the lives of other animals, has largely given way to social influences upon human life. Following Jakob Burkhardt, Fromm contended that individuals began to free themselves

from the social regularities of feudal life during the Renaissance. The conventions of religious and economic life furthered this process, as Max Weber suggested.

These developments posed, however, a serious psychological problem. Without the psychological supports of an ostensibly preordained social order, freedom begat anxiety, what Fromm called "the inability of the individual to stand alone and live."

The ambiguities and ambivalences inherent in this situation led many to escape freedom in psychologically and sociologically unproductive ways. One unproductive response, exemplified in Nazism, involved a masochistic submission to one's social superiors and a sadistic exertion of authority over one's inferiors. Another unproductive response, exemplified in liberal democracies, involved a combination of alienated labor and consumerist social competition, yielding a conformity greater than required by the extant means of social coercion.

In contrast, a productive response would seek what Fromm termed "union with integrity." Such union fulfilled a human need for social engagement while simultaneously providing the conditions necessary for human beings to be not only free from social coercion but also free or able to respond to social life in ways that promoted broadly spiritual growth. This notion of productivity underlay Fromm's explorations of the

psychological preconditions of ethics, the art of loving, and his politics.

FUNCTIONALISM

Functionalism was the predominant underlying theory in both British Social and U.S./American cultural anthropology from the beginning of the 20th century up through the early post–World War II era. Deriving largely from French sociologist Émile Durkheim's work, this school of thought saw societies largely through the lens of an organic metaphor, so that societies were believed to be parallel to living organisms, institutions parallel to bodily organs, and individuals parallel to cells. Like any organism, societies must sustain themselves over time, repair any damaged or diseased parts, and reproduce themselves. The functionalist imperative was to study, through proper scientific observation or fieldwork, the different ways that societies and cultures fulfill these necessary functions.

As a result of their reliance on this organic metaphor, functionalists came to their work with a variety of assumptions. The first functionalist assumption is that all healthy societies and cultures are well integrated and in a state of homeostasis. This meant that most

functionalists assumed that societies and cultures, if left alone, would not change significantly. Instead, change was driven by outside interference. As a result of this assumption, functionalism as a theoretical paradigm was left without any method for studying change, other than to show the ways that a society regains homeostasis after “damage” is incurred from outside influences.

The second assumption is that societies or cultures are best studied synchronically, in one time period, rather than diachronically, or over time. Instead of relying on comparative work or grand theorizing, functionalism demanded of its practitioners that they engage in long-term participant observation to experience life in the society or culture firsthand. The resulting ethnographic writing produced by most functionalists took a “snapshot” view of the society or culture, primarily written in the present tense, the so-called anthropological present, to illustrate the assumed timelessness of what is being presented.

The third functionalist assumption was that the constituent parts of every society, from individuals to the largest political and social institutions, must be seen as interrelated and from a holistic point of view. While variations on this assumption divided British anthropologists from their U.S./American colleagues (see below), the important methodological ramification of this assumption, holism, remained true on both sides of the Atlantic. In other words, all constituent parts of a society must be seen as interacting with and influencing all others. As a result, it was impossible to study, for example, kinship in this paradigm without also looking at religion, politics, subsistence, and all other aspects of society.

Finally, as the name implies, the primary quest for understanding among functionalists was the search for the biosocial or social structural function of any given institution for maintaining the integrity of society. Functionalists assumed that all social institutions or cultural traits, no matter how obscure or seemingly maladaptive, were somehow integral to maintaining the society or culture within the ecological and social contexts in which it existed. Methodologically, this contributed to the development and refinement of anthropological relativism, the belief that all cultures and societies, as well as their constituent traits and institutions, must be looked at in their own context rather than judged by the values and norms of the anthropologist.

Two different kinds of functionalist theory emerged in anthropology fairly early on and served as

the primary split between British Social and U.S./American cultural anthropology. On the British side, A. R. Radcliffe-Brown, proponent of what has been called “structural functionalism,” focused primarily on social structures and their systems of relationships in maintaining a well-integrated society. The structural functionalist school of thought, with contributors such as Meyer Fortes and Sir Raymond Firth, believed that the important level of analysis was society and its constituent institutions and roles. Individuals were seen as largely irrelevant as units of analysis. On the cultural side, Bronislaw Malinowski, one of the earliest functionalist anthropologists, focused his attention on the social and psychological functions of various cultural traits in the reproduction of both individuals and cultures. Malinowski and later U.S./American cultural anthropologists focused primarily on the ways that different cultures fulfilled the biological, psychological, and social needs of individual members, as well as the needs of the cultures themselves to maintain and reproduce themselves. Within cultural anthropology, various forms of functionalism emerged to explore different aspects of these individual and cultural needs, such as cultural ecology and its focus on the adaptation of cultural traits to ecological niches.

Functionalism emerged in reaction to earlier schools of thought in anthropology, primarily those focused on social evolution and the quest for the origins of social institutions and cultural traits, as well as those focused on the spread or diffusion of these institutions and traits. In reaction to the theorizing and historical guesswork of early anthropological work such as that of E. B. Tyler and Lewis Henry Morgan, functionalists abandoned the search for origins and the ranking of all societies in an evolutionary framework. Instead, functionalism developed a mode of synchronic analysis, such that each society or culture was to be studied as bounded and timeless. This

move in the discipline coincided with a greater push toward positivism, the belief in value-free scientific method, and the development of the methods of participant observation.

In turn, functionalism has been criticized and largely abandoned in its purest forms, largely because of its inability to deal with change and history. While the synchronic method of analysis contributed many advancements in the field, such as the abandonment of historical speculation, later anthropologists began to seek ways to combine the strengths of synchrony with historical, or diachronic, views and to include change in their theoretical models. In addition, functionalism’s belief in the possibility of a scientific, objective study of human societies and cultures has likewise caused later anthropologists to turn away from its somewhat mechanistic models and assumptions and toward more interpretive, humanistic, phenomenological, and “postmodern” approaches. At the same time, the functionalist imperatives of primary fieldwork, holism, and the “anthropological present” have continued to be cornerstones of most social and cultural anthropological research and writing to this day.

GAIA HYPOTHESIS

Developed by James Lovelock in his 1979 work, *Gaia: A New Look at Life on Earth*, the Gaia hypothesis offers an understanding of the earth as a living thing, capable of change and transgression. Lovelock named his theory *Gaia* after the Greek goddess responsible for drawing the living world forth from chaos.

The *Gaia hypothesis* suggests that the Earth, or Gaia, is more complex and mystical than anything imaginable. The enormity of the planetary system is something that we can never fully understand and we should acknowledge that when conducting planetary scientific research. The hypothesis also includes an explanation of life systems that exist on Earth. Gaia is not just the biota or the biosphere, but the conjunction of these systems. Gaia as the living planet refers to all parts of the earth: the rocks, the air, and the oceans. Atmospheric and hydraulic systems on the earth are constantly working in balance to maintain conditions necessary for its own continuation.

Because of this process, Lovelock argues that the Earth, similar to a human body, comprises systems that work in conjunction with one another to maintain the whole. If one part of one system is not functional, the others must react to sustain the whole. Lovelock also proposes that if we challenge Gaia and force a different set of conditions, because of clear-cutting forests, for example, the system will regulate itself but not necessarily in a way to support comfortable life for human and animal inhabitants of the Earth.

In essence, the Gaia hypothesis emerged from Lovelock's work with the National Aeronautics and Space Administration (NASA) to detect life on Mars. Through this work, he began to recognize planetary

changes that suggested that planets are not simply stable environments, but living, changing organisms. Its purpose is to offer an understanding of the Earth as an organic system, one that is vulnerable, as any living thing is. Lovelock proposed the existence of a controlling mechanism on earth, one that keeps reactive gases in check, therefore keeping atmospheric and hydraulic conditions relatively constant. The Gaia hypothesis says that when the temperature, oxidation, state, acidity, and aspects of the rocks and waters are kept constant, this homeostasis is maintained by active feedback processes operated automatically and unconsciously by the biota. Many have debated this finding over the years and simply do not see the support for Lovelock's argument that classifies the earth as alive.

For others, the Gaia hypothesis is yet another proposition for how the earth emerged and why it remains the only planet on which life is found. In addition, characterizing the earth as alive recognizes that it is vulnerable. In doing this, one is forced to come to terms with the effects of human actions on a living, breathing planet. However, Lovelock proposes that although Gaia is vulnerable to human activity, it is not fragile. He offers clarification of this point by acknowledging the past devastation that has occurred on the planet and its ability to sustain life despite of this. Gaia is not in jeopardy of collapsing, but changing.

What is the relevance of the Gaia hypothesis today? It offers a holistic approach to understanding the earth as a system. We are not so much interested in the opportunity to prove the hypothesis correct or incorrect, but instead, what it may mean to see the earth as alive. One could argue that weather and natural disasters are examples of Gaia regulating herself in an effort to redirect balance from human impact. As Lovelock stated in 1979, Gaia has changed in the past to restore the imbalance of human activity. There is

no doubt that she will create planetary conditions necessary for the maintenance of her survival.

GALAPAGOS ISLANDS

On the Galapagos Islands, one has the exciting opportunity to walk in the footsteps of Charles Darwin on this primeval archipelago seemingly isolated from the destructive encroachment of human civilization and the ravages of time. This isolated archipelago consists of 15 major islands, along with numerous islets, uplifts, and reefs, located on the equator about 600 miles west of Ecuador in the Pacific Ocean. The “enchanted islands” reveal disturbing facts about this allegedly forgotten world of rock and life, often erroneously depicted as lost in time and enduring beyond the forces of change: The Galapagos flora and fauna struggle in the shadows of active volcanoes to survive against the increasing menaces of recently introduced species, particularly the human animal itself.

Darwin’s eerie “cradle of life” appears as an inhospitable world of lava flows and desolate vistas: a cluster of igneous islands looking like a group of enormous chunks of lunar landscape haphazardly floating upon the swift Humboldt Current. When surrounded by mists and low clouds, these deceptively foreboding islands present a vivid scene reminiscent of our reconstruction of prehistoric times. In fact, this archipelago actually represents a delightful anachronism: present-day life forms eking out an existence in a pristine environment. Fortunately, the inhabitants enjoy a subtropical climate, which is cool, due to fresh trade winds and several capricious ocean currents.

The static first appearance of the Galapagos Islands is an illusion. An extremely strange but special place on the earth, this slowly changing archipelago testifies to the pervasive influences of evolutionary forces. This area of our planet is a geological hot spot of frequent and intensive volcanic eruptions, reflecting the restless and convulsive entrails of the earth: One sees craters, collapsed cliffs, and calderas everywhere. Within this century, wind erosion may finally cause the famous and official geological sentinel of these islands (Pinnacle Rock of Bartolome Bay, which rises 200 feet above sea level) to topple back into the ocean, which waits to once again reclaim its own.

The ages of these islands range from 600,000 years to at least 9 million years. (The discovery of fossil invertebrates and fishes in uplifted marine limestone layers between lava flows allows geologists to date the ancient strata of these rocks.) In fact, this entire archipelago is almost imperceptibly drifting eastward on the Nazca Plate due to tectonic movement. The eastern uplift islands are oldest and may sink back into the sea, while the western volcanic islands may suddenly explode. Yet further geological building is likely to result in the eventual formation of new islands.

On the summit of a volcano on Bartolome Island, 364 feet above the ocean, one experiences the breathtaking panoramic view of a moonlike landscape of craters and spatter cones against the blue ocean. Populations of surface colonizer plants and lava cacti need only soil, moisture, and oxygen to survive in this rugged and demanding volcanic environment.

The Galapagos Islands were the catalyst that inspired Charles Darwin to formulate his theory of biological evolution. When he arrived here in 1835, animals displayed little fear of humans. Over time, the creatures have learned to fear our species. As a national park belonging to Ecuador, this ever-changing archipelago remains a refuge for numerous vulnerable species (especially a wide variety of birds), some found nowhere else on this planet. Winds and waters continue to bring living things to these islands where, as in organic evolution, survival is the exception and extinction is the rule.

Tower Island is a veritable ornithologist’s paradise. This isolated area supports a rich bird population that includes the mockingbird, great and magnificent frigate birds, yellow warbler, red-footed crowned night heron, and the world’s only nocturnal swallow-tailed gull (which is now found throughout this archipelago). On the other islands, one finds the penguin,

pelican, waved albatross, and vermillion flycatcher, as well as the flightless cormorant, red-billed tropicbird, and even the flamingo. The Galapagos also has its own hawk and two species of owl.

Yet the most beloved birds are the masked, red-footed, and blue-footed boobies. The comical appearance along with the humorous sounds and behavior patterns of the blue-footed booby have endeared this particular bird to every visitor of these islands. Like other animals, the boobies often seemed to be deliberately posing for their pictures to be taken.

Throughout this archipelago, the traditionally recognized 14 species of Galapagos finches actually represent a far more complex situation of about 52 distinct overlapping types, with genetic, physical, and behavioral similarities and differences attributed to adaptive radiation, natural selection, and extinction. These enigmatic “Darwin’s finches,” as they are now called, remain a puzzle to evolutionists, particularly taxonomists and geneticists, because certain populations prematurely defined as species are in fact capable of interbreeding. However, other groups of finches are reproductively indifferent, and still others even display altruistic behavior. (The iguanas and tortoises do exhibit clear biological variations to the point of speciation.)

Until recently, all the wild birds and animals had few if any predators and, as a result, were at first unafraid even of humans. As a sad demonstration of their capacity to learn and thereby acquire a new instinct, some finches and iguanas now exhibit a fear of our species (as do other animals among these islands).

The struggle of life on the Galapagos Islands demonstrates both the creative and destructive forces always at work in nature. The fragile ecosystems and precarious niches of this changing archipelago have been drastically altered by recently introduced plants and animals that are harmful to the endemic botanical and zoological specimens; such harmful feral animals include Norway rats, mice, pigs, goats, dogs, cats, horses, cattle, and burros. There have been over 200,000 wild goats on James Island. Of course, the most dangerous animal is the human species, and around 8,000 people now inhabit the Galapagos Islands.

About 600,000 years ago, violent eruptions formed the impressive Alcedo Volcano of Isabela Island, and Charles Darwin himself was the first to describe the resultant double crater. (Strangely, Captain FitzRoy’s own stone engraving marking the historic visit of HMS *Beagle* to this island has never been found.) A population of giant tortoises now lives among streaming fumaroles in this volcano’s wet and grassy caldera valley 1 mile above sea level. In fact, it is possible that a tortoise still survives that was living when the young geologist explored this captivating area in the 19th century. Here, on these lava flows at the base of this shield volcano, one comes close to experiencing the beginning of our earth.

The world’s only seagoing iguana is found at the Galapagos and may even inhabit the same island with the land iguana. The black-red marine iguanas are found in seething colonies camouflaged against lava rocks while basking in the warm equatorial sun. These “imps of darkness” represent an evolutionary shift from land to water adaptation, and they feed on seaweed and marine algae to a depth of 36 feet. They can remain underwater for up to one hour. Retaining a land reptile metabolism, the marine iguanas eject salt water from their systems. The larger brown-yellow land iguanas feed primarily upon the buds and spiny pancake pads that fall from the giant prickly-pear *Opuntia* cactus. They live in colonies, dig burrows, and spend much time basking in the sun.

The Charles Darwin Research Station was established in 1964 at Academy Bay on Santa Cruz Island. Despite its status as a legally protected national park and

wildlife preserve since 1959, the ongoing conservation efforts of this scientific station have not prevented the archipelago from being exploited for personal gain and profit. Unfortunately, international scientists are more destructive than tourists in upsetting the normal natural conditions of the delicately balanced ecosystems and fragile niches throughout these renowned islands. In touching and banding rare birds, as well as netting and branding land iguanas, scientists have altered the total behavior of these life forms and even contributed to many needless deaths.

Fortunately, the Charles Darwin Research Station is successfully taking steps to restore the populations of giant tortoises. These huge reptiles seem like antediluvian animals reminiscent of the age of dinosaurs. One may weight up to 1,000 pounds and live to be 200 years old. In the past, they were killed by the thousands for their meat and the fresh water from their stomachs. Today, there may be less than 15,000 wild tortoises living on these islands.

At the research station, tortoise eggs of this endangered species are incubated and hatched, and the young are raised until they are from 5 to 10 years old, and then released only when they are capable of protecting themselves from predators in their appropriate natural habitats. This scientific station also helps eradicate the introduced pests, conserve other unique species and the differing natural environments of these islands, and maintain *Beagle III* for essential patrolling and communication throughout the archipelago.

The clear Galapagos waters are inhabited by fur seals, sea lions, and green turtles. There are even rays, sharks, dolphins, and whales further out at sea. Coastlines are usually spotted with red Sally Lightfoot crabs. At Tagus Cove (Isabela Island), one finds soft-colored sponges, beautiful cup corals, and brown sea anemones.

Under the Southern Cross, life has been evolving on these islands for millions of years. One may even speak of the evolution of the Galapagos Islands themselves. Yet if incisive measures are not continuously taken, this unique archipelago (as Darwin once knew it) will soon no longer exist. The loss would be irreplaceable. To paraphrase the words of the great naturalist: At the Galapagos Islands, both in space and time, one seems to have been brought somewhat nearer to those first appearances of new beings on this earth.

GALDIKAS, BIRUTÉ MARY F. (1946–)

Perhaps no one knows more about orangutans than the renowned “professor of primates” who has spent more than 30 years in the wilds studying them. Biruté Mary F. Galdikas is a post–World War II baby boomer who has done quite well in the field of anthropology on a national and international basis. No doubt she will continue in her work and make additional substantial contributions. We can be grateful for her efforts to preserve and retain the presence of animals such as orangutans that might have been lost as a result of a lack of concern and insensitivity to the value of their presence among us.

Biruté had an early interest in animals, beginning with her childhood days in Canada. It was an interest in a field of inquiry that would sustain her for the rest of her life. She followed up this childhood interest in animals when she arrived in the United States. In 1966, she received her bachelor’s degree from UCLA, and later received her master’s degree in anthropology from the same institution. It was at UCLA that she met a person who inspired her. He was Dr. Louis Leakey, who was to become her mentor and supporter.

In 1971, Biruté arrived in Indonesia to study orangutans. It wasn’t long before her arduous efforts resulted in substantial new knowledge about apes. Her professional efforts in the field of anthropology have also brought other benefits. Thanks to Biruté, there is a renewed interest in primates as well as a movement to help retain their presence in the world. Yet it is not only the primates that are the beneficiaries

Source: Photo by Richard T. Nowitz/National Geographic/Getty Images.

of her professionalism. Her work has also caused us to be more concerned with the ecological environment that sustains animals and its effect on us as living human beings. Biruté herself has been rewarded in that she was able to establish an impressive publication record concerning her specialized interests. In addition, she has received numerous awards and widespread recognition for her professional activities. Her efforts have also resulted in the establishment of the Orangutan Foundation International in order to bring about a better understanding of primates and the need to retain their existence. She continues to share her vast knowledge and valuable experiences concerning her specialized interests with a new generation of interested students by lecturing at various universities.

BIRUTÉ MARY F. GALDIKAS

Much as with Dian Fossey and the "silverback" gorillas of East Africa, Biruté Galdikas has made her name in natural history by her efforts to protect an endangered species: the Borneo orangutans. These primates had first come to the attention of the world in the 1930s through the buccaneering exploits of Frank Buck, the American explorer and scientist who served as the model for the movie series *Indiana Jones*. In books like *Bring 'Em Back Alive*, Buck not only brought excitement to an America struggling through the Great Depression but also focused attention on the rare wildlife of a wider world.

Galdikas's main concern is the threat to an endangered species through the lust for profit of her fellow humans. While outright poaching or killing of the gorillas incensed Fossey and ultimately caused her death, Galdikas's focus has been the illegal logging taking place in Borneo in Indonesia, which is severely endangering the orangutans' natural habitat. This, according to Galdikas, is in the Kalimantan National Forest. Once again, as with poaching, the motive is profit, as Asian hardwood trees are extremely valuable on the international timber market, where questions are seldom asked as acutely as they should be about the origin of the timber.

Indeed, one of the largest importers of Asian hardwood is the People's Republic of China. China imported about 1.5 billion cubic feet of timber in 2003, more than half of it from Malaysia, Indonesia, and Russia, according to the World Wildlife Fund (WWF). The group said imports are

expected to triple to 4.4 billion cubic feet a year by 2010. While China has acted to preserve its own timber, it has thus grown to be a major importer of hardwood. "Logging bans in China should not lead to forest loss in other parts of the world. Decisive action is needed to ensure that supply chains leading to or through China begin with well-managed forests," WWF international's director general, Claude Martin, said in a statement.

Meanwhile, Galdikas's crusade against illegal logging in Kalimantan continues, as the preserve of her beloved orangutans is continually placed at risk. Fossey, who died trying to preserve the gorillas of Rwanda, and Sister Dorothy Stang, who was murdered while attempting to save the Amazon rain forests of Brazil and its brutalized workers, share a legacy with Galdikas.

GALTON, FRANCIS (1822–1911)

Sir Francis Galton was one of the most influential scientists of his time and is of systematic anthropological and bioethical interest for having introduced into the discussion the idea of eugenics.

Galton was born on February 16, 1822 near Sparbrook, south of Birmingham, England, and was the youngest of seven children of Violetta Darwin and Samuel Tertius Galton. Both came from distinguished families with scientific backgrounds. Already as a child he showed signs of extraordinary talent. Trips to Europe and attendance at different schools within England and abroad were part of his young adolescence. At the age of 16, he began a medical education. In 1840, he started attending lectures on mathematics at Trinity College, Cambridge. It was also during this time that he first experienced the effects of overwork but also discovered his passion for traveling and statistics. In 1844, his father died and left him with money that would finance his future lifestyle. In contrast to his father's wish, he did not finish his medical career. Instead, he spent his time traveling along the Nile together with friends.

Until then, his achievements had hardly been outstanding, but the expeditions into foreign countries set the tone for his future actions. In 1850, Galton followed the example of other famous people of that time and set off to explore Africa, namely, the area around Lake Ngami. After his return to England with a vast number of maps and measurements, he made a name for himself as an excellent cartographer. The Royal Geographical Society honored this work with the annual gold medal and soon made him a fellow of the Society. This was to be the starting point for his scientific career. In the following years, he wrote several books and gave lectures on traveling and basic survival skills, some of which are still in practice in today's army. In 1853, he married Louisa Butler, whose family included some well-known scholars. The marriage of the two quite diverse characters remained without children, but Galton's scientific life became more and more successful. For example, he was made a fellow of the Royal Society and received various other awards also from abroad. His love for statistics and measuring sometimes seemed to wander off in unorthodox directions, for example, when he scrutinized how to make the perfect cup of tea or studied the efficacy of prayer. But it was his unusual approach to a subject that would set him apart from all other scientists.

By coining the term *anti-cyclone* and developing a set of pictorial schemes for weather maps, he also left his mark on meteorology. Another part of his work was concerned with psychology and mental imagery. He also belonged to a group of scientists who published a new weekly magazine on science, literature, and art, *The Reader*. Although this project failed, it can be seen as the predecessor of *Nature* magazine.

He made other important contributions to science, for example, in the field of twin research or by opening an anthropometric laboratory where he gathered detailed information of almost 10,000 people. He also wrote the first systematic study on fingerprints and therefore introduced it as a means of identification. When trying to find a term that concisely illustrated the difference between environmental and hereditary influences on the development of a person, he coined the phrase "nature versus nurture," which is still found in recent debates to refer to that issue. As in many other cases, it was not only the content but also his methods that were new and setting future standards (for example, the questionnaire, the use of statistics or family trees for scientific purposes).

Galton worked on these studies and invented many methods while making his most important contribution to science, which he is famous for even today. In 1864, he published *Hereditary Talent and Character*, a work inspired by his half-cousin Charles Darwin and his work *On The Origin of Species*. Galton claimed that not only physical but also mental features and capabilities are subject to heredity, a thesis that was barely accepted at that time. In addition, he argued that we should improve the human race by allowing only the best to reproduce, just as we breed only those animals that are of good disposition. This idea of selected reproduction he called “viriculture.” From then on, his ambition was to prove his thesis that mental and physical abilities are equally inherited and advocate the idea of viriculture. In his following books, *Hereditary Genius* (1869) and *Inquiries Into Human Faculty* (1883), the topic was further developed. In the latter, he coined the term *Eugenics* (from Greek: *eu* = good; *gignesthai* = to become) to describe the program of improving the human race by letting only the most capable men and women and the more suitable races reproduce. Already in 1869, Galton had formulated the thesis that it is possible to improve the inborn qualities of a race. Thereby, he reassumed an old idea the Greek philosopher Plato (427–347 BC) had already developed in his work *Republic*. Like Plato, Galton found the rationale for eugenic improvement directly in the successes of animal breeding. The prevalence of desirable features in livestock can be increased by selectively mating specimens with the desired trait (for example, in chickens, the increase of their egg production).

Especially toward the end of his life, he found many supporters of his idea of eugenics. In 1904, a research fellowship in eugenics was established at the University in London, and the first Eugenics Record Office was founded. By the late 1920s, some two-dozen American states had enacted sterilization laws according to their new eugenic political agendas. Galton’s ideas were discredited as a result of the German Third Reich and their political agenda of eugenics but were reassumed in 1962 by the Ciba-Symposium in London.

In 1909, shortly before his death, Galton was knighted, and in 1910, he received the highest honor from the Royal Society, the Copley Medal. His work sums up to nine books and more than 200 articles and an unpublished novel. He died January 17, 1911, in Haslemere, Surrey, England. According to his

will, a eugenics chair was established at the University of London.

GANDHI, MAHATMA (1869–1948)

Mohandas Karamchand Gandhi (*Mahatma*), who is discussed in the anthropological literature for his adoption of nonviolent resistance (*Satyagraha*, the vindication of truth by infliction of suffering not

on the opponent, but on oneself), which culminated in the “Quit India” movement against the British in Colonial India, is a modern example of the embodiment of classic Weberian charismatic authority. *Satyagraha*, developed by Gandhi as a way of life, has emerged more popularly as a political tactic, as in civil disobedience movements (Dr. Martin Luther King Jr. and Nelson Mandela). Combining spirituality with popular politics based primarily in interventions, Gandhi was able to rapidly ascend to the helm of nationalist politics in British India and by 1919 earned the title of *Mahatma* (“Great Soul”) from Rabindranath Tagore (Bengali/Indian writer).

Gandhi believed life emerged from a unity of being with no division between the spiritual and the practical. *Ahimsa* (nonviolence) had clear implications for political conflict, specifically violence used against oppression. Such violence Gandhi believed to be wrong and a mistake that would not end injustice, but rather work to inflame the prejudice and fear that fed oppression.

The genealogy of Gandhi’s political and spiritual thought developed during his years in South Africa (1893–1914), where he was hired as a barrister after his education in England. He drew inspiration from the *Bhagavad Gita*, the writings of Leo Tolstoy, John Ruskin, Ralph Waldo Emerson, and Henry David Thoreau. During his formative years as a sociopolitical activist,

he developed concepts and techniques of civil disobedience and nonviolent resistance. For Gandhi, *Satyagraha* emerged as both a creed and tactic and was enacted by declaring opposition to an unjust law, breaking the law, and willingly suffering the consequences.

Upon returning to India, Gandhi joined the Indian National Congress, promoting the movement for independence through civil disobedience and fasting. Gandhi’s economic policy promoted the *swadeshi* movement, the boycott of foreign-made goods, espe-

cially British goods, demonstrated by the advocacy for all Indians to wear *khadi* (homespun cotton cloth). In 1930, he led thousands of people to the sea to collect their own salt rather than pay salt tax (the Salt March).

Recently, scholars have criticized Gandhian politics and rhetoric in four areas. In South Africa, Gandhi’s essays in the *Indian Opinion* have been cited as propagating racist colonial discourse. In contemporary India, he is held as an ideal citizen, based on his Hindu values, which create false and separatist ideals of citizenship for India. Critics also point to his economic policies, which, they argue, only helped the rich and made the poor even more disconnected from the larger national project. Gandhi is most heavily criticized for his stance against women. In his autobiographical statements, he talks about his relationship with his wife, which illustrates a view of women that is demoralizing, vilifying, and, ultimately, colonial.

Despite all criticism, M. K. Gandhi is well respected and remembered for the global legacy of his ideas in the disciplines of religion, philosophy and ethics, political science, economics, geography, and anthropology.

In every society, young people form loose or organized groups or networks around myriads of intertwining and competing interests and practices: It is a normal form of sociality based on generation. Members and outsiders, however, often see and label these formations in different, sometimes contradictory ways. And political institutions may define and public imaginaries understand these groups in ways that determine and justify interventions and programs that help to shape a group's public institutional status and their stake in the overall political process. If formations of groups, networks, or other forms of sociality are normal activities, and if this process is common across historical time and cultural space, then through what epistemological processes should some of them be labeled "gangs," with all that that implies. What is this modern link between the biopolitics of identity and the construction of sociopolitical groupings such that the notion of the gang makes sense? This is the challenge facing social sciences, anthropology included, for there exists an ideological predicament underlying the category "gang" and the phenomenon it purportedly refers to that threatens to subvert its epistemological status. Indeed, gangs as discussed in literature and official reports appear to be a production of the United States's social fabric that is becoming global. It is not surprising that the bulk of the anthropological discussion on gangs uses the materials from and takes place in the United States, and that this commentary is then projected outward into a compressing global space that this commentary is partly responsible for creating.

Though the term was part of the popular sociological vocabulary in Europe by the 18th century, it was not until the 19th century, when the cities of Britain and the United States were reconfigured by mass migrations and the Industrial Revolution, that the term became an established part of the urban lexicon. At this point, the term *gang* was used to identify outcasts, thieves, and other displaced groups considered highly dangerous for order and progress in society. Indeed, by the time Frederic Thrasher, Emory Bogardus, and Herbert Asbury sought to appropriate the term to analytically designate a wide array of delinquent behaviors associated with groups of marginalized youths living primarily in the Chicago, Los Angeles, and New York City ghettos, it had already become deeply engraved in law enforcement vocabularies and the popular imagination. Like gangs themselves, the term has tended to occupy an interstitial space, simultaneously suggesting popular, quasilegal, and analytical theoretical referents.

Thrasher laid down the first systematic work on the phenomenon by providing a cultural ecological framework that defines gangs in terms of the members' potential for criminality and deviance, and explains gang emergence in terms of socioracial marginalization, social disorganization, and shifting populations in poor, isolated neighborhoods. Gangs, he observed, consist primarily of "interstitial groups" of boys "originally formed spontaneously," then integrated through conflict, "more especially in corporate action, in hunting, capture, conflict, flight, and escape." In his view, conflict constitutes a central principle underlying the group dynamics of gangs and their oppositional interactions with larger state/societal institutions. According to Thrasher, fighting with other gangs and the world around them furnishes the occasion to find excitement and thrill that members could not find in mainstream society. Thrasher characterized gangs in cultural terms, with their peculiar language, rules, collective behaviors, symbols, and signs. These cultural but contained worlds are further alienated by their shared conditions and their geographic isolation.

In the United States, the Great Depression, World War II, and then the flow of African Americans from the South to the major cities of the North led to profound structural transformations that were accompanied by increasing poverty, drug use, and growing urban marginalization—conditions ripe for criminal gang development. So by the second half of the 20th century, analysts, many sponsored by

government grants, overwhelmingly conducted “gang studies” under criminological and juvenile delinquency premises. Urban policy development heavily inflected the formulation of research questions. Researchers placed emphasis on how the young boys who are recruited into gang activities develop “frustration.” Robert Merton and Albert Cohen’s work underlined that such frustrations were the result of “blocked opportunities.” Accordingly, gang members in their experience of “status frustration” search to develop an alternative ensemble of values and cultural practices that set them apart from the rest of society and provide them with the identity and status they crave. The research questions from this period generated a new line of studies of gangs that placed the concept of subculture at the center of its analytical strategy. For example, Walter Miller suggested that lower-class subculture constitutes a fertile milieu that breeds delinquency. Other researchers have argued, however, that the notion of subculture has never really shaken off the ambiguity surrounding it.

By the mid 1980s, gang activity, along with drug trafficking and violent crime rates, were being made more visible to the general public through the media, law enforcement reports, and politicians. Crime-conscious citizens became alarmed and stated their growing concerns regarding law and order in their cities. Fear of crime, combined with a “moral panic” about gangs and drugs in inner-city neighborhoods, influenced what Richard Quinney identified as the “formulation and application of criminal definitions, the development of patterns related to criminal definitions, and the construction of criminal conceptions” of gangs as social reality. Youths, primarily black and Hispanic immigrants and natives, living in U.S. ghettos where criminality and gangs were perceived as developing and thriving, became the primary empirical unit for large-scale surveys and sociological investigations. But these rather formulaic “outsider” approaches were soon exhausted, and theorists began to search for alternative ways to conceptualize gangs.

In this vein, new qualitative perspectives on gangs and gang members began to generate a more thorough description of processes and activities. Not least, the evidence showed that both the internal structure of gangs and their external relationship to mainstream society was extremely variegated and could not be reduced to any predetermined formula. Joan Moore provided anthropological descriptions of gangs that tackled some of the common stereotypes

put forward by public discourses and media representations. Among other things, her ethnographic work helped destabilize several stereotypes that inform public representations of law enforcement reports on gangs and gang members, including female memberships in gangs and modes of sociability among gang members that do not fit the stereotypes of “they’re all drug users and criminals.” Drawing from William Julius Wilson’s work on the inner city and the underclass and Douglas Massey and Nancy Denton’s on segregation in U.S. cities, and applying the ethnographic field research method, anthropologists demonstrated how the underclass predicament and racial segregation deny residents from U.S. ghettos economic opportunity and political integration. Ethnographic researchers like Elijah Anderson, Joan Moore, Felix Padilla, and John Hagedorn investigated how the growth of the urban underclass combined with socioracial segregation to perpetuate the reproduction of particular street identities with their code (Anderson), mechanisms of social isolation (Moore), and ethnic marginalization with particular Hispanic identity challenges (Padilla, Hagedorn, Vigil). J. Diego Vigil’s concept of “choloization” (the mechanism through which social isolation alienates Chicano youth from mainstream society) allowed him to capture the ways in which the streets provide alternative avenues for socialization to Chicano youths in Los Angeles. In his view, Chicano youths are experiencing redundant and multiple levels of marginality from social institutions, their families, and themselves. Multiple marginality, Vigil argues, generates for marginal youths an integrated framework that “combines sociogenic and psychogenic elements and actions.” After gathering data on ethnicity of incarcerated youths (who are overwhelmingly blacks and Hispanics) and the rate of gang members among them who are imprisoned, ethnographic studies conducted by researchers like Joan Moore and Loic Wacquant helped establish the importance of carceral institutions in producing structural relations between prison and the streets. Anthropologists Scott Decker and Barrick Van Winkle explored through ethnographic methods the relationships between family, friendship networks, and violence among gang members. The study shed light on humane aspects of gang members, reinforcing Daniel Monti’s argument that gangs are not alien to the social world. Indeed, according to Monti, “gangs are merely one among many types of groups” that people create to structure their lives. The

anthropological approach on gangs had opened new explorations on the use of gender and masculinity in gang formation as well as on ethnicity, culture, and gang membership, thereby shedding light on the complexity of the gang phenomenon.

The process of alternative street socialization, what has been called the “underground economy,” constitutes a critical area of investigation for anthropologists, such as Philippe Bourgois and Felix Padilla Sudhir Vankatesh. The scale of gang involvement in the underground economy, while largely reported by law enforcement institutions and the media, has yet to be scientifically established, despite the growing interest and body of research on the business of gangs. Although alternative definitions exist on what constitutes gang entrepreneurial activity, there is ethnographic evidence that points toward a positive relationship between gang membership and drug trafficking. Some have focused on how gang entrepreneurial activities have mediated the relationships between gangs and their surrounding communities. Others like Martín Sánchez Jankowski went one step further to stress that a gang’s dialectical connection with its larger community was key to its survival.

Gangs as a social phenomenon have captured the interest of the public as well as educational, political, and social institutions throughout the United States. Fueled by more visible gang activity in other nations, increasing opportunities for researchers to speak freely (that is, without political reprisal) about local gangs, and growing awareness of the value of studying gangs and allocation of resources in this direction, other countries are producing sizable bibliographies on gang life, particularly in South America, Australia, the Caribbean, Europe, and Southeast Asia. In Brazil, anthropologist Alba Zaluar suggests that the involvement of youth gangs cannot solely be explained by poverty and marginalization. There is growing evidence, she contends, that young males in gangs are mostly driven by a “hypermasculinity,” fed by the performance of gang celebrity figures in the media. This can be captured, although tangentially, in Paulo Lins Ribeiro’s *Cidade de Deus* (City of God), which gave rise to the movie with the same name. Youth gang, masculinity, and globalization are also thematized to think about gang formation and gang processes in other countries or across countries. White, for example, found that a great bulk of gangs in Melbourne, Australia, are “social gangs,” wannabees that try to redefine the “cool pause” and “tough guys”

in the mean streets projected in the media and reported in ethnography of gangs in the United States. In France, Colette Pétonnet produced one of the most powerful ethnographies of marginalized young people in a *banlieue* of Paris. *On est tous dans le brouillard* (We are all in the fog) decrypts how institutional politics articulate public representations and fear of the youths of the *banlieue*. Pétonnet used ethnography to destabilize public perceptions of these youths, who tend to be mostly Algerian descents and whose marginalized conditions estrange them from the sociocultural benefits that the society claims belong to everybody in the name of the republic. In Southeast Asia and the Caribbean, emerging studies are trying to unfold the intertwining between the globalization process, new configurations of inequalities, and formations of gangs as a locus of resistance. Haiti and Honduras epitomize the quintessence of how larger transnational politics and global economics may shape young people’s lives in a way that criminality seems to be the shortcut for accomplishing their goals. While other countries have long histories of youth groups developing in various forms, ethnographic studies of countries in the Caribbean, such as Honduras and Haiti, have linked the deportation of convicted young offenders to the rise of gangs outside the United States. While in the United States, these offenders presumably mastered the technologies of gangs sufficiently to reconstitute the same organization upon return to their countries of origin. These deported youths, however, need to be situated within the larger sociopolitical context of civil war and political instabilities of their home countries and to which the United States has been an active protagonist.

Given the extensive history of gangs in the United States and the origin of gangs in other countries being attributed to the United States, the international research community has built upon the U.S. bibliography on gangs and is currently extending it in directions similar to those currently being pursued within the United States. This provides a common perspective on gang that is utilized as an entryway to think about marginality, delinquency, and the exotic other’s cultural adaptation to the larger society (for example, young Algerians living in parts of France or young Vietnamese and Lebanese immigrants residing in Australia). This circulation of concepts between researchers in the United States and those in the rest of the world is concomitant with the global circulation of fear of gangs in these same societies and

people's simultaneous fascination of the youths characterized as comprising these "ethnic gangs." American projection of its popular culture, epitomized through movies on "gangs," MTV, gangsta rap, and other forms of commodified venues, which lead to a globalization of youth cultural practices in different segments of societies in the world, is happening at the same time that literature on gangs in the United States constitutes the primary references for researchers, policymakers, and social workers in other countries that already feel affected by youth gang problems, particularly crime, violence, drug use, and delinquency. Nonetheless, it is still worth asking whether youth in other countries are simply adopting the American concept of the gang or whether, correlatively, the socioeconomic and political conditions for the production of gangs are now evolving in those nations, leading to sociohistorically specific versions of what has become a globally modular form.

Gangs have had, and continue to play, a key role in the politics of the modern, stranger-based nation-state. In many countries, politicians have cited the presence of gangs and the need to control their behavior as part of a law and order platform but also to help mobilize voters to support a particular candidate. Politicians and state authorities have enlisted and sometimes funded gangs to function as unofficial arms of state policy and to suppress civil society opposition in ways outlawed to the police. In some cases, from South Africa to the Americas, gangs have been employed to intimidate and sometimes kill opposition candidates. Gangs have also appeared as ways to defend the community from state action or to serve as a community-based police in the absence of state law and order power. In these cases, gangs provide protection in ways that police either will not or cannot provide, though they may impose their burdens on the community, such as a tax/ransom for their services. Yet the importance of local histories and contexts as well as their articulations with the global process are critical to be understood for anthropologists to situate youth group formation as well as youth involvement in gangs in these countries.

Because of its condition of emergence, the concept of gangs has dubious epistemological status, since it is invested by morality and politics and structured by popular and scientific constructions as well as institutional stakes. It performs by creating its own reality. The analytical concept "gang," while imprecise and therefore incapable of rendering

explicit the sociological unit it intends to describe and of defining the behaviors it vows itself to translate, becomes what Pierre Bourdieu called a "realized" category, in the sense that it analytically encompasses American cultural definitions of gang—definitions that conflate popular ideas of race, class, and gender—and thereby offers an open flank for contestation and struggle of classification. For example, in the United States, three young individuals standing on a street corner may go unnoticed. If these same three individuals were black and the street corner was situated in a poor neighborhood, they likely would call the attention of both the gang researcher and the police. What constitutes a gang is neither exact nor is it static.

Today, the anthropology of gang faces key issues related to definitions and conceptualization. The use of the concept of culture in describing gang behavior or gang cultural practices is, at best, in the United States, a shortcut for "race." In the field of gang research, anthropologists enter a complex semiotic terrain in which the very concept that defines their perspectives, the concept of culture, condenses a number of tenets held by gang researchers from many disciplinary (and political) perspectives. Moreover, anthropologists in their search for a new epistemology of gang studies must investigate the extent to which the concept of gang itself is culturally bounded, despite (and maybe because of) the abundant scholarship gang studies have generated. The anthropology of gangs should strive to render explicit the implicit meanings that underlie the concerns and questions generated by citizens and scientists alike in their fear of gangs and the cultural practices that are associated with it. The conceptualization of gangs as youth cultural practices in anthropology must attempt to deghettoize its strategy in order to relate the dynamic relationship the phenomenon refers to with the global political economy.

GEERTZ, CLIFFORD (1926–)

For the last 40 years, Clifford James Geertz has been the most influential and controversial anthropologist to capture the interest of both scholars and the general public. In contrast to the works of most anthropologists, Geertz's books, now numbering 19 individually authored and edited volumes that have been translated into 21 languages, are widely debated by anthropologists, historians, literary critics, political scientists, and other scholars. Since 1967, he has been a regular contributor to the *New York Review of Books*. Not since Margaret Mead has there been another anthropologist to engender such scholarly debate and to be incorporated into popular culture.

Underlying Geertz's symbolic approach to anthropology is his attention to philosophy. He was trained at Antioch with an BA degree in philosophy in 1950 and then was graduated with a PhD in anthropology from Harvard University in 1956. Drawing primarily on the humanities, he advocates using a variety of methodological and theoretical practices to study and understand culture in its own terms. His theory of culture as a system of symbols and meanings that are publicly exhibited in objects and actions and an interpretive strategy of regarding culture as text hold

Source: Reprinted with permission from the *Annual Review of Anthropology*, 31, copyright © 2002 by Annual Reviews, www.annualreviews.org.

wide sway in contemporary anthropological analyses and literary criticism. According to him, the goal is to understand these texts within the same cultural context as the natives, in order to learn the local meaning. Ethnographies, like any other cultural expression, should be understood as texts to be read alongside the natives' own texts. His detractors view this as moving anthropology from a scientific orientation to one that is based on metaphorical and literary techniques, in which science and scholarship, in general, are rhetorical. Some have claimed that he influenced anthropologists since the 1970s to write about other societies rather than collect and analyze data.

Although Geertz has influenced anthropological scholarship to include interpretive and hermeneutic models of analysis, he is a consummate ethnographic fieldworker. He has conducted ethnographic research in Java since 1952, Bali since 1957, and Morocco since 1963, periodically revisiting these locations of the past 50 years. Most of this research was conducted while a faculty member in the University of Chicago Anthropology department, from 1960 to 1970, and then as a

faculty member of the School of Social Science Institute for Advanced Study until his retirement in 2000.

Geertz's ethnographic research has mainly centered on religion, first publishing on the topic in 1960 with the monograph, *The Religion of Java*, and then later in 1968, with *Islam Observed: Religious Development in Morocco and Indonesia*. In 1963, he published *Peddlers and Princes*, which analyzes economic development and cultural change in Indonesia. Geertz's most influential work, *The Interpretation of Cultures* (1973), is a collection of essays, which best exemplify his interpretive and humanistic approaches to anthropology. Subsequent collections of essays, *Local Knowledge: Further Essays in Interpretive Anthropology* (1983); *After the Fact: Two Countries, Four Decades, One Anthropologist* (1995); and *Available Light: Anthropological Reflections on Philosophical Topics* (2000) remain true to the rhetorical and philosophical approaches that Geertz employed to theoretically frame and interrogate his own ethnographic research and that of others in *The Interpretation of Cultures*. These works should not be seen as a rehashing of ideas, but as Geertz's distinctive ruminations and critical perspectives on his own life, the use of theory, the practice of anthropology, and contemporary culture.

Gemeinschaft, or “community,” has always been an ambiguous notion. Particularly in the German context, it has been contrasted with the term *Gesellschaft* (society). Both notions represent aspects of the

Ancient Greek term *κοινωνία*, the historical background of which is identical to “society.”

In German, the term can turn up in connection with family, village, city, profession, or religion. Often, *Gemeinschaft* (community) and *Gemeinde* (rural commune or parish) have been used as synonyms.

According to Kant, the ambiguity of the notion of community is such that it can be translated as *communio* as well as *commercium*, whereby the first stands for a formal negation of individuation while the second represents a proper relationship, a reciprocal influence, and the participation of individuals within a whole, which as dynamic community is ahead of solely local communities. Kant concentrates on the logical and metaphysical aspect of the notion. More important and influential is the moral and political meaning of the term.

Ferdinand Toennies

Toennies's work *Gemeinschaft und Gesellschaft* (Community and Society) contains the most influential discussion of these terms for German sociological theory. His description of a community is summarized as follows.

According to Toennies, communities are based upon organic relationships, whereas societies presuppose ideal relationships, by which he does not mean that relationships in a society cannot get improved, but that they are dependent on contracts, which were made between individuals.

The basic constituent of a community is the family, and the family analogously turns up at all levels of a community. The most basic relationships of a family are the following: First, mother-child relationship; second, husband-wife relationship; and third, the relationship between brothers and sisters. As a consequence, Toennies holds that if one studies a house, then one studies a community. A house consists of three layers, the inner, with husband and wife; the descendants and their spouses; and the outer sphere, which involves others. The next-larger group of a community is the clan, or the large family, which involves all distant relatives and relatives of relatives. It is structured analogously to the family, and so is the town, and the city. In this context, Toennies does not refer to really large cities, as it is difficult to uphold a family-like, organic structure in these.

Besides discussing the various levels of a community, Toennies further explains what it is that allows

men to form close bonds. It is obvious for him that blood, location, and spirit or character are especially important for men. The best communities are therefore based upon these aspects. These three aspects are closely interconnected, and they correspond to the human relationships of relatives, neighbors, and friends. With one's relatives, one shares the blood, with one's neighbors the location, and with one's friends the character. Family, friendship, and neighborhood are reached best by means of conventional sociability, which one can find in houses, towns, and cities.

Yet there are other relationships as well that are important for men, like that which one has in a guild, a brotherhood, or a religious community. In all of these, people share something that is particularly valuable for them, something basic to their character. In all of these groups, people form certain hierarchies, and the student, or anyone on a lower level, has respect for the dignity of the more advanced, the master of the respective profession. Here, Toennies employs the term *dignity* in a traditional sense. Dignity, *Wuerde* in German, is related to worth (*Wert*), and only someone special can be worthy and can have value. Nowadays, the term, particularly in Germany, is mostly used in a much wider sense, whereby it is attributed to all human beings. Toennies not only refers to the dignity of spirit, but expands the concept to other areas as well. Any kind of superiority, Toennies calls dignity. He distinguishes further between a dignity of age, strength, and spirit or wisdom. The superior do not abuse their superiority, but as Toennies stresses, within a bodily-organic relationship, there is an instinctual naive tenderness of the strong toward the weak, a generous will to help and protect them.

As a consequence of this mutual help, people feel safe and at home. In addition, one feels close to others, as one was born into the community, grows up in it, and is therefore familiar with all the practices traditionally performed there. This feeling of safety is also achieved in families, with neighbors, and with friends. Most men feel most serene and happy when they are together with their family. Neighborhoods allow people to form close bonds, as one is used to the others, one sees, helps, and gets to know them. One is familiar with their history, and one shares certain habits on which living together is based. Friendship is based on character, a similar way of thinking about things. Not only does this enable people to feel a bond between the various members of a community, but one also knows that these bonds are not instable, but

rather long-lasting, real, strong, and alive. Such bonds are possible only within a community, as one can feel sympathy and be happy with others only if one understands others' characters. The consensus of a community consists in its common unifying character, and understanding presupposes an intimate knowledge of one another.

Related to the great amount of common features is the importance attributed to art and religion in communities, as both are concerned with the life of the people and matters regarding character, and values. The traditions of both religion and art are best sustained in families and can therefore be well promoted in a community. However, in the same way as families support the flourishing of art and religion, they, in return, help to preserve the idea of a family and to keep it alive.

Toennies's understanding of a community bears many similarities to Aristotle's πόλις (city/state). In both theories, the most fundamental aspect is the family, which is there for the everyday wants of human beings. In the family, various types of relationship can be distinguished. Aristotle stresses the husband/wife, parents/children, and master/slave relationship, whereas Toennies refers to the mother/child relationship, husband/wife relationship, and the relationship between brothers and sisters. However, according to both, a clear hierarchical structure can be found both in the family, as well as in all other ideal types of social system. In addition, both stress the importance of a natural organic structure. Aristotle even gives a detailed account of the various levels of a city-state. According to him, several families united form a village to aim at more than their daily needs. When several villages are united to form a self-sufficient whole, the state comes into existence, for the sake of the good life.

Communitarianism

In the contemporary debate, many thinkers who stress the importance of common aspects within a social system and are referred to as "communitarians" mention Aristotle in order to support their own positions. In general, one can distinguish two main types of communitarians. First, there are the "right-communitarians," who stress the relevance of common values and, like Toennies, point out that this leads to a hierarchical system. The most prominent right-communitarian thinker is A. MacIntyre. Within

the German context, there is a tendency to associate right-communitarianism with fascism, as people hold that each theory that tries to attain worldly power and has a detailed account of what is good concerning all relevant aspects of human life has to oppress the people and force them into a specific shape that does not take into consideration the specific nature of each individual. Second, there are the left-communitarians who demand stronger common values but combine these with equality. Many of these thinkers also have sympathies for communism. The most famous thinkers here are M. Nussbaum and C. Taylor.

MacIntyre holds that it would be best if we returned to an Aristotelian, neo-Thomistic type of Christianity. He sees modernity as a descent, and the Enlightenment as a moving away from the true Christian faith, which enables human beings to give order to their lives and the state. The Christian religion in its adequate form is supposed to help all the people to live a free and good life. MacIntyre's concept of freedom is a positive one rather than a negative one, which is being upheld by liberal thinkers. Positive freedom implies that one holds the true concept of the good, which one integrates in the political sphere so that it can help the people make the right choices, the choices necessary for living a good life. Negative freedom, on the other hand, implies an absence of constraint, as long as one does not intrude into the freedom of other human beings.

MacIntyre holds a strong, detailed, and inclusive concept of the "good." It is strong, as it includes all relevant human aspects, both with respect to public as well as private matters. A weak concept of the good does not include all relevant human aspects. It is detailed, as it puts forward a clear, many-layered description of the aspect in question. A vague concept of the good gives open hints instead of a specific description. It is inclusive, as it is valid for the political as well as the religious sphere. An exclusive concept of the good would be in favour of a separation of the political and the religious spheres.

Nussbaum, like MacIntyre, is a neo-Aristotelian, and in contrast to him, she holds a strong, but vague and exclusive, concept of the good. Her essentialist concept is based on two separate intuitive lists. The first gives a description of the *conditio humana* and lists 10 points that are relevant for all human beings (mortality, the human body, cognition, early childhood development, practical reason, community with other human beings, relationship to other species and

nature, humor and play, individuality). The second list states abilities important for all human lives (live through all stages of life, health, sexual satisfaction, avoid pain, have a concept of the good, solidarity). Her concept is strong, as it deals with all relevant human aspects, but it is also vague, so that it leaves open the negative freedom for individuals to adapt the aspects to their own needs. In addition, it is exclusive, so that it can be applied in the various regions of the world.

In contrast to the other two communitarian thinkers, C. Taylor does not hold a strong concept of the good. He is in favor of a pluralist ethics, but in a world that is being interpreted in a Catholic manner, which is the reason why his position is detailed at least in one aspect. His writings are particularly noteworthy for his criticism of human atomism, which according to him is associated with both liberalism and libertarianism.

Although communitarianism is fairly strong in the present, there are also many liberals and libertarians. Both hold a weak, vague, and exclusive concept of the good. The most important liberal thinker is J. Rawls. He is the author of *A Theory of Justice*. Even more liberal is the libertarian R. Nozick, who achieved fame with his *Anarchy, State, and Utopia*. In the history of philosophy, there have also been quite a few vehement critics of community. M. Stirner particularly upheld the importance of singularity in contrast to the community. According to F. Nietzsche, each community eventually has to make men common, but by being common, one becomes base and does not fulfill one's natural drive for power and excellence.

 GENDER

Gender is a social and cultural categorization defined by the meanings given to biological differences between the sexes. Gender roles are the social skills, abilities, and ways of acting thought appropriate to members of a society depending upon their sex.

Since the 1970s, there has been a growing anthropological interest in the construction of gender relations and the significance attached to gender. Anthropologists compare the similarities and differences found in various societies and look for explanations for them. The way in which gender intersects with other kinds of “difference” has become another focus of the work on gender.

History of the Gender Category in Anthropology

Until the 1970s, few anthropologists had given detailed attention to gender (Margaret Mead was one of the few). But in the 1970s, feminist anthropology started to investigate women’s situations in different social, political, and economic order; the roots of women’s subordination; and the general roles of women in different cultures and economies. In the 1980s, the focus shifted from “women” to “gender.” “Gender” appeared to provide the key for talking about sex/gender differences without relying upon linked dichotomies based on Western ideas, which were seen as culturally specific. As the focus shifted from “women” to “gender,” “men” and “masculinity” also came to be studied in their own right and investigated as cultural constructions. Both were considered as complex and changing categories, with masculinity itself viewed as just as problematic as femininity. Finally, during the 1990s, the distinction between sex and gender itself became murky. Increasingly, studies presented the sexed body itself as historically and culturally constructed.

Traditional Gender Roles

In Western and some non-Western societies, gender roles are traditionally strictly divided into feminine and masculine and are assigned to males and females at latest at the moment of birth. Powerful cultural mechanisms operate to ensure that “boys will be boys and girls will be girls.” The process of training girls to

be feminine and boys to be masculine is largely unconscious. Boys are supposed to grow up to be powerful, to hide their weaknesses, to be independent, demanding, and aggressive. Occupations thought appropriate for men are therefore mainly in politics, economics, and sports. Girls are encouraged to be good mothers and expected to become what is needed to fulfill this role, such as being giving, emotional, and intuitive. They are expected to sacrifice their ambitions and personal needs in order to please and care for others. If they do not adhere to these gender roles—if they are, for example, ambitious, demanding, and tough or rough—they are considered unfeminine. Males who do not evince the expected traits of masculinity are called “feminine” or “effeminate.” As the system is a hierarchical one, these men and boys are degraded. Although these roles have diversified, gender roles limit what men and women can feel, think, and do.

Gender and Biology/Nature

Is gender determined by biology/nature, or is it the result of culturally given meanings to biological sex differences? Many cultures have a “natural attitude” with respect to gender. This attitude is made up of the assumptions that (a) gender behavior is the result of sex, not the result of cultural interpretations; (b) that there are only two genders; and (c) that one’s gender is invariant and permanent. The question is not settled, but the data demonstrating that a gendered behavior is unquestionably biologically determined do not exist today.

The simple picture is complicated by the fact that biological sex itself is not set on a simple male/female switch, but may be composed of a variety of chromosomal and morphological “anomalies.” Biological conditions in which a child’s genetic sex (chromosomes) and phenotypical sex (genital appearance) do not match, or are somehow different from the “standard” male or female, are called *intersex*.

Gender Crossing, Third Genders

There are people who feel that their true gender is at variance with their biological sex. Some have sex change surgery or undergo medical treatment aimed at changing their sexual anatomy. These people are termed *transsexual*. Others take on opposite gender roles without changing their sex. The best-known case in the ethnographic literature is the so-called

berdache, found in a number of societies indigenous to North America. *Berdaches* are individuals who take on gender roles in opposition to their anatomical sex by adopting the dress and performing the activities of members of the other group. The case of berdache and other cases raise the questions of whether we should think of such phenomena in terms of a basic two-gender system, with the possibility of individuals transferring from one to the other, or whether it is more appropriate to think of them as constituting a distinct third gender. Among the Hijras of northern India, for example, males who dress in women's clothing and act more like women than men are considered neither male nor female.

Cross-Cultural Perspectives

Ethnographic evidence supports the notion that gender is a cross-cultural phenomenon, and the vast majority of individuals can easily be differentiated into sex classes on the basis of their genitalia. Nevertheless, in looking at different societies, past and present, anthropology has discovered a wide range of variation in gender construction and gender roles, in the value placed on activities performed by men and women, and in men's and women's access to important social resources.

Gender and the Future of Anthropology

There are now few if any areas of anthropological inquiry that have not been subjected to a "gendered" inquiry. Gender is an element in theories of biological, cultural, and linguistic anthropology, and of archaeology. The range covered by gender questions has come to parallel that of anthropology itself. The way in which gender intersects with other kinds of "differences," such as race, class, ethnicity, sexual preference, and physical ability, has become another focus of the work on gender. Although a woman may not outrank a man of her class, she may outrank men of lower classes. Nevertheless, some go as far as to argue that women and men do not exist anywhere, and therefore the responsible anthropologist will not even assume that there are women and men or third genders in a given culture until it has been shown that these are relevant social categories.

GENE DISTRIBUTIONS

The analysis of gene distributions throughout the world, called *population genetics*, is very important for estimating the date when human life originated and the timing and direction of human migrations throughout world history. Before DNA, the analysis of fossil remains was the major way of estimating human origins. With genetics, four major evolutionary forces are considered: mutations, genetic drift, gene flow, and natural selection.

Within anthropology, there has been an intense debate between the multiregionalists, who believe that humans evolved roughly simultaneously in multiple regions of the world, and the out-of-Africa proponents who believe that current human life originated in Africa. Based on their research on mutations, which shows much more genetic variation within Africa than within other regions of the world, geneticists support the African origins school. Because genetic mutations (and hence genetic diversity) happen randomly throughout history, by a process of extrapolation backward, the conclusion is, comparatively speaking, that a group with a larger number of mutations has had a longer time period in which to accumulate mutations and thus is older.

Mutations have also been very important in studying migrations and explaining gene distributions in different groups and regions of the world. Luigi Luca Cavalli-Sforza, a prominent population geneticist in the United States, has published much data showing the genetic distances between nationality groups and the genetic distance between ethnic groups throughout the world. The more genetic distance between groups, the more mutations have occurred to cause the distancing, and hence the further back one goes to find their common ancestors.

Brian Sykes has classified nearly all women in the world into one of seven groups, each having genetic similarities from ancient history. He showed how these seven groups are distributed throughout the world and suggested the migration history of the groups based on differences and similarities between the genetic compositions of the groups. Genetic research has shown that males and females have very different migration patterns, with the female more likely to leave her parental family and follow the male's family pattern.

For males, a selected number of markers (specific positions on the Y chromosome that are unique and can be measured) can be grouped together into haplotypes, and a number of similar haplotypes can be grouped into haplogroups, to show genetic relationships between different groups or geographical areas of the world. There are strong correlations between haplogroups and regions of the world. Each marker is given a DYS#, which stands for DNA Y-chromosome segment number, numbers that are increasingly being standardized and used internationally so that comparisons between different studies can be made more easily. A world database using nine markers (<http://www.yhrd.org>), for example, has haplotypes for over 25,000 males, allowing any of these men to see where they have nine-marker genetic matches from over 200 sites throughout the world. The less two men have mutated, the closer they match, and the more recently their MRCA (most recent common ancestor) lived.

Genetic drift affects a small population that does not have sufficient population size to randomly reproduce all the genes of its parent population. A principle called the Hardy-Weinberg Law says that genetic frequencies will not change (that is, changes will balance themselves out) in an infinitely large population with random mating. But, a small group can become nonrepresentative of its parent generation because of inability to reproduce all the previous genes. Hence, two small groups that come from the same parent population will, over time, develop dissimilar gene distributions as each loses some genes and moves further from its original gene distribution. Different mutations can also add to the genetic distance between the small populations.

A *bottleneck*, a catastrophe such as war or disease that kills or stops the reproduction of a significant number of people, also increases genetic drift if it results in only a small group to reproduce. The founder effect, when a small group of people, or even

one male or one female, begin a group that then multiplies greatly, also minimizes the genetic diversity of a group and increases the possibility of genetic drift. The founder effect also can be found among groups, such as Amish in the United States, who isolate themselves geographically or socially. This usually increases cousin marriages, which increases the likelihood of negative recessive genes being activated and can increase the likelihood of some diseases.

Gene flow is the introduction of genes into a group that previously did not have those genes. This usually results from migration of one group into another group's territory (if reproduction results), but it also can result from the mutual interaction and reproduction of two genetic populations. It can be voluntary or involuntary, although most gene flow has occurred very slowly over history. Over time, a new group can develop that is unique and differs from both of the original groups.

Natural selection is based on the principles that not all individuals survive and reproduce, and that some individuals have characteristics that increase their chances of survival and hence these successful characteristics become more common in a population. The fitness and probable survival of the population thus is increased. But environments change, perhaps rapidly, so the success or lack of success of a characteristic can change. Social attitudes can change definitions of what is rewarded, or even persecuted. Mutations can introduce variations that can increase or decrease an individual's chances of survival.

Figuring out the relative contributions of these four forces and when each had an impact can be very difficult, and controversies remain. The rate or frequency of mutations is still debatable, with important potential effects on the amount of time one goes backward to estimate a significant event. Genetic engineering is a new force, with unknown potentials and questions. DNA research has added a new layer of knowledge to fields such as genealogy, archaeology, and cultural history. Molecular archaeology, molecular anthropology, genetic archaeology, or genetic anthropology are new terms that might describe emerging new interdisciplinary approaches to gene distributions and related concepts.

GENE FLOW

Gene flow is the transfer of genes from one population to another population, usually by migration of one population into the other population's territory. Descriptively, it is also referred to as gene migration, gene admixture, interbreeding, or gene exchange between populations.

Almost always, gene flow refers to migration taking place primarily in one direction. It is necessary that one group not only move into another group's area, but that the new group also reproduce with the group into which it migrates. Dispersal of one population into another population does not lead to gene flow if there is not reproduction between the two groups. In effect, new genes are introduced into the population into which the new group moves, and the two groups hence become more similar genetically over time.

Genetic drift (random changes in gene frequency within a small population, resulting in mutations) and sometimes natural selection tend to introduce more diversity between groups, but gene flow tends to decrease genetic differences between two groups. If gene flow is not opposed, over time, the two involved groups can develop a new genetic group, which can be unique, genetically located between the previous genetic composition of the two involved groups.

Gene flow can occur rapidly and can involve a large movement of one population into another population distantly located, sometimes with force involved, but history suggests that gene flow more likely has occurred with continuous slow movement of individuals of one population into another neighboring population. Contemporary human populations are relatively homogeneous genetically, suggesting that gene flow has been a major factor. Luigi Luca Cavalli-Sforza and his

colleagues have shown that there is a strong relationship between geographic and genetic similarity (or, conversely, dissimilarity), suggesting that people frequently are genetically close to their neighbors. Gene flow is not the only reason for this, but frequently is a major reason.

Lack of gene flow also can characterize groups that have a small amount of genetic interchange with their neighbors, sometimes because one or more groups in an area want to remain separate identities. Eastern European Jewish males, for example, with an emphasis on maintaining their religion, averaged only about 1/2 of 1% of gene flow into their community per generation for about 50 generations.

Social relations between two groups can affect the speed and extent of gene flow. In the United States, for example, about 30% of people who identify as African Americans have White European male genetic backgrounds. This significant input of White European genes into the African American population is due largely to oppression of African Americans by European Americans, mostly of British background, under slavery. Native Americans also experienced significant gene flow, frequently following violent conquest, into their group by European Americans, mostly of Spanish background. Racial, ethnic, religious, and social class differences also can impede gene flow by discouraging reproduction between the groups.

GENERATIVE GRAMMAR

Generative grammar is a theory of language that is generally said to have made its appearance in 1957,

with Noam Chomsky's *Syntactic Structures*. It is often contrasted with structural or taxonomic grammars. While the aim of structural grammar was to account for all the data in a given corpus, the aim of generative grammar was to *generate* any sentence in a given language, including those not yet uttered. Thus, the goal shifted from accounting for a body of data to modeling the mental functioning that allows humans to use language creatively. Put another way (Chomsky's), the goal shifted from the description of observed language behavior to the explanation of the observed behavior in terms of the mental states of language users.

In its early phase, generative linguists used a huge number of transformational rules to generate different surface sentences from the same underlying sentence. For example, the basic sentence *Mary saw the cat* can be transformed by different rules into a passive (*The cat was seen by Mary*), a yes-no question (*Did Mary see the cat?*), and various "Wh" questions (*Who saw the cat? What did Mary see?*). The grammars linguists tried to write using these rules were enormous and yet still incomplete, and the proliferation of rules made it difficult to explain the rapid and effortless way in which children, by the age of 3 or so, acquire the grammar of their language. As a corrective, generativists attempted to reduce the number of rules by developing general ones, such as *merge*, which allows smaller elements to combine into larger ones, and *move*, which accounts for the position of *what* in *What did Mary see?*

For a simple illustration of the power of generative grammar, take the noun phrase (NP) *the gray cat*. This phrase is generated by first merging the adjective *gray* and the noun *cat* to yield *gray cat*, which can then be merged with the determiner *the*. Using the traditional rewrite rules this looks like:

NP → Det N'

N' → Adj N

N: *cat*

Adj: *gray*

Det: *the*

Adding lexical items to the N, Adj, and Det lists very rapidly increases the number of NPs that can be generated. For example, adding the indefinite determiner *a(n)*, the nouns *dog* and *goat*, and the

adjectives *black* and *white* increases the number of potential NPs from one to 18.

More recently, generative linguists have incorporated *principles* and *parameters*. Principles are invariant; the *projection principle*, for example, requires that any properties of the lexical head of a phrase apply to the whole phrase. So, if the noun *woman* is [+human], the NP *the first woman in space* is also [+human].

Parameters require language learners to make a choice. For example, in English, verbs precede their objects: *eat + potatoes*. In some languages, like Aymara, objects come first: *ch'uq* (potatoes) + *man-q'aña* (eat). This illustrates the *head parameter*: the heads of phrases may either precede or follow their complements. Once children "set" this parameter, they know other facts about their language:

Head complement

Verb phrase *eat potatoes*

Prepositional phrase *in the house*

Adjective phrase *afraid of spiders*

Noun phrase *president of the United States*

One of the claims of generative grammarians is that because language is innate, the forms that human languages can take are sharply constrained. This claim created some tension between these linguists and followers of the earlier tradition in linguistic anthropology that took languages to be infinitely variable and entirely determined by culture.

GENETIC DRIFT

One of the conditions of the Hardy-Weinberg equilibrium (the set of circumstances under which evolution does *not* occur) is that the population of breeding individuals is large enough that chance will not alter the allele frequency from one generation to another. When the population is small, however, all but one allele of each gene tends to go extinct. In a population with 20 females, for instance, for each gene with two equally common alleles, there is more than a 75% chance one or the other allele will be lost within 50 generations, independent of any selection. This chance variation in allele frequency in small populations is called *genetic drift*.

Drift can be enormously important. The most common scenario for speciation involves geographic isolation of a population. This typically occurs when individuals invade a new habitat or are cut off from the rest of the species at one corner of its range. These isolated populations are likely to be small, and they may well by chance be missing some alleles even before genetic drift can take place. The consequence of this kind of biased start in a subpopulation is called the *founder effect*. The same thing happens when a local population is reduced in size from disease, climate change, or habitat alteration—the so-called genetic bottleneck. Alleles not surviving the bottleneck event, the founding of a population, or subsequent genetic drift are simply lost.

In many cases, the rapid evolution (changes in allele frequency) of a population is caused by genetic drift and selection taking place simultaneously: Isolated populations or populations drastically reduced by external factors are typically subject to unusual selection pressures. The challenges of a new or marginal habitat, different diseases and parasites, or an altered climate select for novel allele combinations. Selection and genetic drift, taken together, seem to account for most of the cases in which an isolated population becomes unable to reproduce with the parent population by the time contact is reestablished. Reproductive isolation is the essential final step in speciation.

GENETIC ENGINEERING

Genetic engineering denotes the process of changing the genetic constitution of cells by introducing, modifying, or eliminating specific genes through modern molecular biology techniques. It is applied in several fields, including medicine and agriculture. Its application in medicine comprises the production of medical substances in genetically modified organisms, genetically modified animals as models for the study of human diseases, and gene therapy. In agriculture, it is used to improve food products in a variety of ways. Some of the well-known genetically modified foods are rice, soybeans, carrots, and tomatoes. Genetic engineering has not only become a major topic of biological anthropology, but has important implications on cultural and social anthropology as well; the most controversial issue is the direct nonmedical application of genetic engineering techniques to enhance normal function in humans.

Cells, DNA, and Genes

In the midst of the 19th century, modern biology was born on the basis of Charles Darwin's theory of evolution and the finding that all living organisms are composed of cells. In the second half of that century, important discoveries were made in the fields of genetics and embryology, culminating at the turn of the century with the chromosome theory of heredity, which claims chromosomes are the structures that carry heredity information. From that point on, genetic research thrived. The chemical nature of the chromosomes, however, was unknown until 1944, when Oswald Avery and his colleagues used bacteria to demonstrate that genetic material is composed by *deoxyribonucleic acid* (DNA), which is found in all living organisms. In complex cells, DNA exists in the nucleus in the form of chromosomes (nuclear DNA) and in the mitochondria, structures found in the cytoplasm of cells (mitochondrial DNA). But without

knowledge of the structure of DNA, little could be understood about how it actually worked.

This changed in 1953 with the discoveries by Jim Watson and Francis Crick. They could show that DNA is organized into two combined strands in the form of a helix, the now famous *double helix*. The strands are built by four bases only: adenine (A), guanine (G), cytosine (C), and thymine (T). These are linked together with sugar units and phosphates. Moreover, the two strands are complementary: The sequence of the bases of one strand determines unequivocally the sequence of the other, due to the chemical affinity of the bases. Base pairs can form *only* between A and T and between G and C. This is essential to DNA's ability to duplicate and make an exact copy of itself (a process called *replication*). In this process, the two halves of the helix separate, and a new partner is fabricated to match each half exactly.

DNA controls unique features of an organism. Each cell of an organism contains the exact same DNA sequence, in which the instructions for certain gene products are encoded. There are systems in cells that read the DNA sequence and “translate” it into *proteins* (linked amino acids). Proteins then go on to be effective in many ways. Some are structural components of tissues (like collagen, a structural material of bone and many other tissues). Some are enzymes that initiate and enhance chemical reactions (like lactase for digestion). DNA contains the instructions, and proteins carry out the instructions. The process by which the DNA instructions are converted into the structures and functions of a cell is called *gene expression*. The rule by which the DNA sequence is translated into a protein is called the *genetic code*. This code is the same in all known living organisms. An organism's life, growth, and unique features depend on its DNA. A segment of DNA coding for defined information is called a *gene*. All the genetic material of an individual or species is called its *genome*.

In many species, however, only a small fraction of the genome's total sequence encodes protein. And with those that do, not all information is actually used for protein synthesis. Contained within DNA sequences are elements, known as *promoters* and *repressors*, which allow individual cells to control which genes are expressed. Expressing genes in the

appropriate tissue at the appropriate time is very important. In the human body, for example, regulation ensures that fingernails grow only on fingers and hair grows only on specific parts of skin. But although genes determine many characteristics of an organism, we do not yet understand how specific genes contribute to the complex physical, cognitive, emotional, and behavioral traits of humans.

Types and Techniques of Genetic Modification

The alteration of DNA allows genetic engineers to change the genetic constitution of cells. Since DNA is passed on from one generation to the next, changes in DNA can be carried over generations. In this respect, however, an important distinction in genetic engineering occurs between *germ line* and *non-germ-line* cells. In most organisms, certain cells are set aside exclusively for reproduction. These are called *germ line cells* (in humans, the eggs and sperm). Non-germ-line cells are all the other cells in the body, muscle cells, skin cells, liver, and so on. If a genetic modification does not alter germ line cells, it has no effect on the genetic makeup of future generations. Genetic engineering is performed on germ line or non-germ-line cells, depending on the purpose of intervention.

Two basic types of genetic modification are the addition or deletion of function. To add a function to a cell, all that must be done is to introduce a new gene that codes for the given function. Deletion of

function can be performed by either *knocking out* a gene or introducing an *antisense gene* to interfere with the cell's ability to express a given gene. Although genetic engineering has a wide range of applications, only a few fundamental steps are required. These include the isolation of the donor DNA of interest and its amplification, transfer, and expression in a host cell.

The major tools for the *isolation* of the donor DNA are so-called restriction enzymes. They work by cutting up the DNA, a process called *restriction*. Most of them are very specific. They recognize short, specific sequences in DNA and cut at specific points within these sequences. For most tasks, the amount of DNA fragments that can be obtained from a cell is not enough; amplification is needed. Therefore, one of the most important practical developments in genetic engineering is the *polymerase chain reaction* (PCR), an achievement for which its inventor, Kary Mullis, was honored with the Nobel Prize in Chemistry. Using PCR, any short sequence of DNA can be amplified many times. Because even single DNA molecules can be amplified through PCR, the method is also applied in archaeology, forensic anthropology (the application of anthropological techniques to legal matters), and paleoanthropology (the study of earlier hominids). For example, anthropologists have been able to analyze mitochondrial DNA sequences of the Neandertals.

There are a number of techniques for introducing genes artificially into host organisms. Some use biological vectors (organisms to transport donor DNA), like plasmids or viruses. Plasmids are small circular pieces of genetic material found in bacteria that have the ability to cross species boundaries. Viruses are infectious particles, specialized over millions of years, that contain genetic material to which a new gene can be added. The vector DNA and the fragmented donor DNA are brought together. Afterward, the new combination of DNA in the vector is transferred into the cells of a host organism, in which the cells with the new genetic information are reproduced and the new genetic information is expressed. Such techniques have been around since the 1970s. Nonbiological methods of transfer comprise chemical and physical procedures. In *electro- and chemical poration*, pores or holes in a cell membrane are created to allow entry of the new genes. The method is now widely used with microorganisms, plants, and animals. So-called projectile methods use metal, such as gold, slivers, which are coated with the genetic material to be transferred.

One projectile method, called *biolistics*, propels the coated slivers into the cell using a shot gun. This method has become the main method of choice for the genetic engineering of many plant species. Another method, used especially with animals, introduces DNA into a cell via *microinjection*: The genetic material containing the donor DNA is directly injected into the host cell by use of a fine-tipped glass needle. With some methods, the means by which genes are inserted in the host organism may be inexact and occur at random. Therefore, methods have been developed to insert genes at specific spots in the genome of even complex organisms. *Recombinase-mediated cassette exchange* (RMCE), for example, performs site-specific chromosomal integration in mammalian cells. The expression in the host organism becomes predictable, because a single copy of the DNA inserted into the genome is integrated at a known site. Several types of bacteria are favored as host cells, but higher organisms, such as fungi, yeasts, mammalian, or insect cells, and whole animals or plants, can also be transformed by foreign DNA.

Since DNA is universal among organisms, it can be transferred between unrelated organisms. Genetic engineering enables scientists to create plants, animals, and microorganisms by manipulating genes in a way that does not occur naturally. It even allows genes to be moved across species lines or to move artificially constructed genes. An organism into which foreign DNA has been introduced is called a *transgenic organism*. The transfer of genes across distinct species is called *horizontal gene transfer*. While in theory, the technology is available to transfer a particular gene from any organism into any other, in actual practice, there are numerous constraining factors. The single most limiting factor is the dearth of basic scientific knowledge of gene structure and function.

Applications of Genetic Engineering

Techniques of genetic engineering are applied in both the research and practice of medicine. In practice, for many years, genetic engineering has made it easier to gain various medical substances that are produced by bacteria, such as insulin, for example. As explained above, plasmids augmented with new genetic material can move across microbial cell boundaries and place the new genetic material next to the bacterium's own genes. Often, the bacteria will take up the gene and begin to produce the protein for which the gene

codes. If the new gene codes for insulin, the bacterium will begin to produce insulin. In addition, transgenic animals are used to produce medicine through the process known as *gene pharming*. Genetically altered sheep, for example, produce an enzyme in their milk that is present in most people and prevents a serious form of emphysema. Extracted from the milk and purified, it can be helpful to people who do not normally produce it. In general, genetic engineering provides the basis for a well-founded biological-causal understanding of certain diseases, thus opening up the development of new effective treatments oriented on the cellular-molecular causes of a disease. These are the hopes of *gene therapy*. Gene therapy is a technique for correcting defective genes responsible for disease development. Such therapies often try to replace or repair defective genes. In most gene therapy studies, a “normal” gene is inserted into the genome to replace an “abnormal,” disease-causing gene. Hopes are high for some diseases (Parkinson’s or Huntington’s, for example), but gene therapy is still experimental. When gene therapy does not alter the germ line but only somatic cells (*somatic gene therapy*), the disease can still be inherited by children. In contrast, this is no longer possible when gene therapy is applied on the germ line level (*germ cell gene therapy*). At the moment, germ cell gene therapy is banned in many countries. The same holds for xenotransplantation, the transplantation of tissues and organs between species (for example, the use of a swine heart for a human). Here, genetic engineering plays a crucial role, because in order for this technique to work, it is necessary to knock out most of the strong, ordinary antigenic systems in swine. In medical research, transgenic animals have become important models for the study of human diseases, like cancer, multiple sclerosis, and diabetes. Due to its physiological closeness to man and its simple breeding, the mouse is the most common transgenic animal. However, there are also transgenic strains of farm animals, such as chickens, pigs, sheep, goats, and cattle.

Genetic engineering techniques have also been used to improve food products in a variety of ways. Some of the well-known genetically modified foods include rice, soybeans, carrots, and tomatoes. In agriculture, useful plants are optimized by genetic engineering through the addition of a resistance against pesticides or resistance against pests. Sometimes genes are transferred to add other useful characteristics in growing. Tomatoes are an example. These are

sensitive to frost, and this shortens their growing season. Fish, on the other hand, can survive in very cold water. Scientists identified a particular gene that enables a flounder to resist cold and used the technology of genetic engineering to insert this “antifreeze” gene into a tomato. This makes it possible to extend the growing season of the tomato. Sometimes, genes are added to provide extra nutrients, like in “golden rice,” a genetically modified rice that contains building blocks for vitamin A. Deficiency in this vitamin causes blindness and other diseases. Moreover, sometimes a gene is removed to enhance a product, such as removing the tear-producing element of onions.

Cattle and pigs are commonly treated with genetically engineered growth hormones to increase growth rates. A lot of other industries use genetically engineered products as well. For example, genetically engineered enzymes are used in the production of cheese and bread, in laundry soap, in the bleaching of jeans, and in the treatment of leather.

Genetic Engineering and Anthropology

What is already possible and what is probable to be possible in the future are both related to anthropology in various fields and ways. Biological anthropology includes the exploration of the implications of modern advances in genetics, including genetic engineering. For anthropological research, genetic engineering is a method to explore basic biological mechanisms, such as yet unknown principles of genetics. Biological anthropology also places particular emphasis on the interaction between biology and culture; for biological anthropologists, genetic engineering will help in understanding the complex relationship between biological constitution, culture, and environment. On a more future-oriented and general level, it is questioned whether genetic engineering poses evolutionary dangers and how it will change the understanding of evolution itself, what it is, and how it operates. Will traditional evolution be replaced by “intelligent design”? Will genetic engineering change the relationship between humans and other species? However, biological anthropology is not the only field concerned with genetic engineering. Social and cultural anthropology are interested in the social and cultural implications of genetic engineering. Genetic engineering is controversial due to numerous questions related to product safety, and environmental and social concerns. Many aspects are still poorly

understood and unexpected side effects may occur. More controversial still is the direct application of genetic engineering techniques on humans and especially the possible nonmedical applications for the enhancement of normal functions. Some see genetic engineering as a new tool for eugenics, the doctrine or practice of selective breeding in order to “improve” the human genetic pool. The effect genetic engineering will have on societies is a huge field of anthropological study.

GENETIC ENGINEERING

Genetic engineering, including the completion of the historic Human Genome Project, has promised to bring the end of suffering to many who are victims of inherited genetic disorders, from diabetes to cystic fibrosis. By mapping the human gene sequences, researchers hope to unlock the keys that may in time wipe out genetic diseases that have blighted the lives of untold generations of humanity. Unfortunately, as with atomic energy, which gave the world new diagnostic and treatment tools in medicine as well as weapons to annihilate humankind, genetic engineering has become a two-edged sword.

While many researchers have devoted their careers to genetic engineering to improve the lives of men and women, others have worked equally hard to develop genetically engineered biological weapons. Perhaps no one has revealed this dark side of genetic engineering better than the Russian defector Ken Alibek, born Kanatjan Alibekov in now-independent Kazakhstan in 1950. In 1992, Alibek defected to the United States after having served as the first deputy chief of Biopreparat, the Soviet state organization dedicated to the development of biological weapons for use in war. Coincidentally, the greatest period of Soviet research into biological warfare, according to Alibek, took place after 1972, when Moscow endorsed the Biological Weapons Convention, which was meant to remove that scourge from the military arsenals of the world.

In simple terms, genetic engineering in biological weapons was to be used to increase the strength—and lethality—of bacteria, viruses, and other microbes that were known to exist in nature. Such experiments were carried out in the Soviet Union at great risk. In 1979, an anthrax outbreak took place as a result of a plant accident at Sverdlovsk, where Boris Yeltsin, later president of a non-Communist Russia, was the official in charge of the area. An example of genetic engineering for biological warfare took place when the dreaded Ebola virus was genetically “spliced” into smallpox to create a more lethal pathogen, or germ. Ebola, which created panic when it erupted in Kikwit, Congo, in 1975, was not considered a good risk as a biological weapon, or agent, because those who contracted the disease died too soon to spread it to many other potential victims. By splicing Ebola onto smallpox, the scientists at Biopreparat succeeded in developing a pathogen that took longer to kill its suffering victims—thus giving them more time to infect others.

Thirteen years after Alibek’s defection, the real extent of Russia’s biological weapons program is still unknown. Furthermore, those research scientists who have lost their employment as a result of the continued serious state of the Russian economy are now feared to be offering their deadly expertise to a foe far less predictable and far less inclined to act rationally than the former Soviet Union: the Islamic extremists of al Qaeda and its allied jihadist groups.

— John F. Murphy Jr.

STEM CELL RESEARCH

The announcement in 1998 of the isolation of human embryonic stem (ES) cells by James A. Thomson at the University of Wisconsin at Madison was greeted with controversial reactions. On one hand, the discovery promised great medical benefits, as it ensured an endless reserve of transplantable cells, offering hopes to people suffering from diseases such as Parkinson's and diabetes. On the other hand, it also provoked horrified responses, mainly from conservative religious circles, because of the embryonic and fetal sources of these cells. As a result of pressure from the Vatican and influential religious groups, stem cell research has been banned in several countries, while, in the United States, it does not receive any public funding.

The stem cells isolated by Thomson and his colleagues came from "spare embryos." These embryos, called blastocysts, have been created in a fertility clinic by in vitro fertilization but are no longer needed for transfer to a woman. The outer level of the blastocyst is destined to become the placenta. The remainder of the blastocyst, called the inner cell mass, is what will then become the fetus. Embryonic stem cells are isolated from this inner cell mass and this has raised ethical questions on the moral status of the embryo and the aborted fetus. These questions prompted Pope John Paul II to issue a statement of strong moral condemnation for "procedures that exploit living human embryos and fetuses—sometimes 'produced' for this purpose by in vitro fertilization—either to be used as 'biological material' or as providers of organs or tissues for transplants in the treatment of certain diseases. The killing of innocent human creatures, even if carried out to help others, constitutes an absolutely unacceptable act." This position clearly derives from the view that the human fetus is a person. This view was explicitly put forward by the Pope in his 2005 address to Vatican ambassadors: "The human embryo is a subject identical to the human being which will be born at the term of its development."

The debate over stem cells has given rise to some paradoxical situations. The most evident is the American case where in which President George

W. Bush ordered that federal funding for research be limited to embryonic stem-cell lines already in existence, and that it not be used on any new cell lines created from donated surplus embryos. No limits have been put on private research.

— Luca Prono

GENETICS, HISTORY OF

In its broadest sense, genetics is the science of biological variation. It focuses on variation that results from inheritance, the process by which characters are passed from parents to their offspring. This often places genetics in contrast to the environment, even though one is not sufficient without the other. For thousands of years, humans have been interested in how characters are inherited in plants, animals, and themselves. Much was learned over the centuries through observations and repetition of what seemed to work in agriculture and animal breeding. But it took an Austrian monk working in the middle of the 19th century to conceptualize what was happening when characters were passed on. The monk, of course, was Gregor Mendel, and we are now more than a century and a half into the discipline he fathered.

The history of genetics has been colored by the best and the worst of times. The field has suffered through periods of extreme controversy. Its practitioners have varied from those whose ideas could not help but be controversial given the views of the society in which they emerged, to those who quietly worked in their laboratories to develop the theories and technologies to drive the engine of genetics. Both scientific and societal concerns have driven the swings of the so-called nature-nurture pendulum (see figure). *Nature versus nurture* refers to the influences of biology, that is, genetics, versus the environment, in the determination of characters, be they physical or behavioral. The swings of the pendulum reflect periods of time during which the scientific community and society viewed either nature or nurture as the more important determinant. These swings have clearly influenced developments in genetics and will be highlighted as we trace the history of this science.

The following history of genetics covers first its roots in the 19th century. The next period, 1900 to 1953,

Swings of the nature-nurture pendulum.

Source: Adapted from Plomin, R., & Petrill, S. A. (1997). Genetics and intelligence: What's new? In *Intelligence*, 24, 53–77, copyright © 1997, reprinted by permission of Elsevier.

spans from the rediscovery and promotion of Mendel's seminal work to the discovery of the basic structure of deoxyribonucleic acid (DNA) in 1953 and the beginnings of molecular genetics. Next, a special section addresses the eugenics movement that began in the 19th century and slowly disintegrated in the aftermath of World War II. Finally, from the 1950s to the present day, the field of molecular genetics developed and tremendously influenced the way all of genetics is practiced, leading to the current era of genomics.

The 19th Century: Roots of Genetics

The names of three individuals dominate the 19th century relative to the roots of genetics: Charles Darwin, Gregor Mendel, and Francis Galton. In 1859, Charles Darwin was the first to present scientific evidence for what he called *natural selection* in his book *On the Origin of Species*. Met with skepticism, Darwin's theory profoundly influenced the ideas of scientists and geneticists of future generations, perhaps having more impact than any other naturalist on the course of genetics and society. However, Darwin never produced a satisfactory explanation for the genetic source of variation in characters that he understood to be the target of selection.

Only 6 years after Darwin's publication, Mendel published his papers regarding inheritance of characters in peas, which seems to have been virtually

ignored by scientists of his time. His work was so advanced that it wasn't until its rediscovery in 1900 by three scientists that the results were finally understood. Between Mendel's initial publications during the 1860s and the rediscovery of his work, the third individual began his work.

Francis Galton, a cousin of Charles Darwin, and just as much a naturalist as Darwin, became the pioneer for the promotion of *eugenics*, a term that he coined, the direct meaning of which is "well-born." In 1865, Galton opined that if as much effort and cost went toward improving biological variation in humans as was spent on breeding improvements in farm animals, we could surely improve humankind's cognitive abilities. Galton thought that biological inheritance of leadership qualities determined the social status of Britain's ruling classes, seemingly a logical extension of Darwin's theory of evolution.

However, whereas Darwin never discussed the nonscientific impact of his ideas in the face of society, Galton advocated them. Furthering Galton's naturalistic view of the world, the Englishman Herbert Spencer introduced the concept of Social Darwinism. He drew analogies between society and biological organisms in a book that sold more than 400,000 copies between 1860 and 1903. Using the principle of evolution as a universal law and considering competition as the key to evolutionary progress, Spencer ignited a society that wholeheartedly believed that government welfare interfered with the evolutionary process by favoring survival of the unfit. At the time, however, there was a lack of scientific knowledge about how the inheritance of specific traits occurred, and without the immediate results to confirm Spencer's and Galton's ideas, the public essentially lost interest. This was all about to change with the rediscovery of Mendel's experiments and the explanation of how characters were passed from parent to offspring.

1900–1953: Classical Genetics

Many pioneers in biology, only some of whom will be highlighted here, led the early work in genetics. At the turn of the century, research in genetics had greatly accelerated, and explanations for the transmission of traits were being found through the rediscovery of

Mendel's work. While Hugo de Vries and Erich von Tschermak were initially given credit as having independently rediscovered Mendel's work, their publications are now judged to have been vague. Some think they might have misunderstood Mendel's concepts. It was a third scientist, Carl Correns, who was able to demonstrate clearly how Mendelian ratios were derived theoretically. He indicated that discrete units, known eventually as *genes*, somehow factored into causing the traits observed in offspring. This exciting rediscovery of Mendel's work fueled the younger generation of geneticists because Mendel's laws served as a foundation for predicting the transmission of characters from parents to offspring.

As a consequence of the interest in and promotion of Mendel's ideas after the turn of the 20th century, two opposing scientific groups developed. One saw Mendel's ideas as providing the prime basis of explanation for the inheritance of characters and came to be known as the *Mendelists*. The other, known as *biometricians*, had its origins in the work of Galton on metric traits such as height and did not think that Mendelian principles offered the models to explain the inheritance of these traits. William Bateson led the Mendelists, while the statistician Karl Pearson and Walter F. R. Weldon led the biometricians. Ultimately, most geneticists of the time would reconcile the differences between the Mendelians and the biometricians. The culmination came in 1918, when Ronald A. Fisher published his classic paper showing that characters controlled by large numbers of Mendelian factors (genes) would show the type of continuous, quantitative distribution (normal bell-shaped curve) and correlations between family members like parents and offspring that Galton and later the biometricians described. This publication marks the beginnings of classical quantitative genetics, the analysis of the genetics of metric characters such as height, head length, and the like.

In the early 1900s, population genetics, the study of how genes are distributed and maintained in populations, had its beginning. In 1908, G. H. Hardy published a paper in the journal *Science* regarding the application of mathematical methods to biology. Hardy explained how the frequencies of genes in populations would remain the same from one generation to the next unless certain forces, now known as the mechanisms of evolutionary change, were operable in the population. That same year, Wilhelm Weinberg, publishing in German, stated the same principles as Hardy.

Gregor Mendel

Starting in the second decade of the 20th century, the mathematical basis and theories of population genetics were further developed by three individuals. Fisher has already been mentioned. Between 1922 and 1929, he developed a theory of evolution in which he combined Mendelian inheritance and Darwin's natural selection. During this period, he published several papers that led to the eventual culmination of his ideas in the book, *The Genetical Theory of Natural Selection*, in 1930. About the same time as Fisher, an English biologist, J. B. S. Haldane, was beginning his career. A paper published in 1915 by Haldane was the first to show genetic linkage in mammals. After returning to England from World War I, Haldane continued his research in population genetics. His publications from 1924 through 1932, and lectures presented in 1931, titled "A Re-Examination of Darwinism," led to the book *The Causes of Evolution* in 1932.

Sewall Wright, an American, was the third in the group of major contributors to population genetics. He was an early user of the principles of Hardy and Weinberg. He is probably best known today for having stressed the importance of random genetic drift as an explanation for changes in gene frequencies in small populations. Wright lived well into his 90s and contributed immensely to the theoretical development of

population genetics for more than 70 years, an extraordinary accomplishment. Fisher, Haldane, and Wright were essential to the vitality of population genetics from the 1920s and well beyond. They were conscientious enough to consider with an open mind not only evolutionary genetics but also the effects of environment on heredity. This was vastly different from the scientists who promulgated eugenics, who viewed the effects of heredity as primary.

Another major force in the development of genetics during the 1920s was Hermann J. Muller. His paper on "Artificial Transmutation of a Gene" was published in 1927 in *Science*. Earlier, Muller had worked in the lab of Thomas Hunt Morgan at Columbia University. Morgan and his students and coworkers originated the use of the fruit fly *Drosophila* in research to study the mechanisms of inheritance. In 1915, Morgan's research group published the important text, *The Mechanism of Mendelian Heredity*. After leaving Columbia in 1920 for the University of Texas, Muller became interested in the mutagenic effects of X-rays. His subsequent experiments leading to the paper in 1927 were the first time any laboratory had been able to cause a permanent, heritable change in the genes of an organism. Muller's work convinced him that almost all mutations are deleterious.

For many years, Mendelian genetics and Darwinian evolution were viewed by the geneticists of the day as two disparate entities. Fisher, Haldane, and Wright were the first to alter this thinking. However, their work was heavily mathematical and often difficult for biologists and others to comprehend. Into this situation came the Russian-born naturalist and geneticist, Theodosius Dobzhansky, and his book *Genetics and the Origin of Species*, in 1937. This was the first blow to be struck for the Evolutionary Synthesis, the melding of Darwinian and Mendelian thought with its application and testing in the field, the natural laboratories of population genetics and evolution.

Other architects of the Evolutionary Synthesis continued this work. Several publications, directly inspired by Dobzhansky's book, appeared in the 1940s. Ernst Mayr's book *Systematics and the Origin of Species* (1942) focused more specifically on systematics and the problem of speciation, a concept poorly understood by many biologists of the time. George Gaylord Simpson's *Tempo and Mode in Evolution* (1944) tied in evolutionary change from a paleontological viewpoint. Finally, G. L. Stebbins's *Variation and Evolution in Plants* (1950) broadened the synthesis

to include botanical studies and plant genetics. These works together helped unify and strengthen Dobzhansky's original thesis and provided the basis for further developments in the Evolutionary Synthesis that impacted many fields of study, including biological anthropology and the study of human evolution.

Although the developing eugenics movement, discussed in the next section, applied genetics to human variation, it was not the only means by which human genetics began to develop. Some of the earliest attempts to apply Mendelian principles to human characters occurred in the early 1900s. An example of this was the description by the English physician Archibald Garrod of the first metabolic disease in humans, alkaptonuria, as being inherited in an autosomal recessive manner, meaning that both parents were carriers of the mutation for this disease and would pass it on with a one-quarter chance of transmission with each child.

Human genetics was already developing as a field during the first three decades of the 20th century, but it was not until the 1930s that it began to shed the baggage of eugenics. Garrod continued to form the basis for human biochemical genetics with his book *The Inborn Factors in Disease* in 1931. Three years later, Asbjörn Følling described phenylketonuria (PKU), one of the classic metabolic diseases. The first study of human identical twins, by Horatio H. Newman and his coworkers, was published in 1932. The same year Haldane made the first estimations for the mutation rate of a human disease gene, that for hemophilia. Fisher was also applying population genetics principles to human genetics with the publication in 1934 of a major work on ascertainment and linkage studies in human pedigrees. 1935 marked the publication of the book *Principles of Heredity* by Laurence H. Snyder, who was at the same time establishing a research program for human genetics at Ohio State University.

Beginning in the 1930s and continuing throughout the 1940s, there were signs that genetics would develop into a biochemistry-based and eventually molecular-based science. Muller's work on X-ray mutagenesis had stimulated a search for the chemical basis of mutation and at least two lines of research. The first began in an interesting fashion and illustrates that genetics, indeed any science, has sometimes relied on luck for advancement. This research was to broaden understanding of gene function and was contributed by Charlotte Auerbach and her colleagues. Auerbach, born a German Jew, left the increasingly threatening situation in Germany in 1933. She soon

held a position in genetics research at the Institute of Animal Genetics in Edinburgh, Scotland. Muller visited the Institute in 1938 and is credited with suggesting research on chemical mutagenesis to Auerbach before his departure to America.

Auerbach and her coworkers began to study the effect of mustard gas on the mutation rate of the fruit fly *Drosophila melanogaster* in 1940. They hoped to find a way to perform a directed mutation to enable studies of the nature of the gene. Mustard gas induced similar mutations to X-rays but produced more lethal mutations. The anticipated directed mutation did not materialize. Because of World War II, the results were not published until 1946. The delay did not dull the significance of the work. Further discoveries of other chemical mutagens, stemming from Auerbach's work, showed the desired directed mutation effect and proved to be invaluable to genetic research.

In the second direction taken from Muller's work, George Beadle and Edward Tatum in 1941 used *Neurospora conidia* treated with X-rays to revolutionize the way that geneticists searched for metabolic mutants. After treatment with ionizing radiation, these researchers grew each spore in two different media. The first, the complete media, contained everything a cell would need for optimal growth; the second, the minimal media, provided only the barest essentials for cellular survival. Once a spore was found that could survive on complete but not on minimal media, progressive metabolic precursors could be added to the minimal media to determine exactly what metabolic pathway had been disrupted at what point. Their findings seemed to show that one gene is responsible for the production of one, and only one, enzyme. Beadle and Tatum proposed the "one gene, one enzyme hypothesis," the first biochemical explanation for the function of the gene. Beadle and Tatum contributed two additional innovations. The first was the establishment of *Neurospora* as a microorganism ideally suited for genetic studies. This was crucial groundwork toward eventually making bacteria genetically useful in the laboratory. The most important innovation was the linking of the genes of the organism with its biochemistry, essentially establishing molecular genetics, or *biochemical genetics*, a term that Beadle preferred.

Another research discovery of the 1940s found its origins in a classic 1928 paper in which Fred Griffith reported that serological types of the bacteria pneumococcus were interchangeable. Specifically, it was shown that rough-coated pneumococci could

be permanently transformed into the more virulent smooth-coated cocci capable of causing lethal infections. At the time that study was published, the laboratory directed by Oswald T. Avery in the Rockefeller Hospital of New York City had already been working with pneumococcus for over 15 years. Given his familiarity with the microorganism, Avery became convinced that the phenomena described by Griffith held the key to how pneumococci controlled the formation of the bacterial capsule.

Determining the nature of this key to pneumococcal virulence would take an additional 16 years, before Avery, Colin M. MacLeod, and Maclyn McCarty published their classic 1944 paper, "Studies on the Chemical Nature of the Substance Inducing Transformation of Pneumococcal Types," in the *Journal of Experimental Medicine*. In this meticulous, carefully analyzed study, the authors discussed the revolutionary evidence that DNA is the transforming principle that influences the construction of the capsule of the pneumococcus in a heritable way. The significance of this work was the idea that it is DNA, not nucleoprotein, that is the conveyor of inheritance in living things. It was truly a major shot toward initiating the DNA revolution.

The Eugenics Movement

Eugenics represents a special case in the history of genetics, as its advocates and practitioners had such a profound influence on genetics during its development as a science. The eugenics movement spanned the period from the late 19th century until well into the 20th century. As mentioned, it was Galton who coined the term *eugenics* in 1883 as the process of improving the human race through selective breeding. The idea of saving humankind from a perceived genetic and moral decline hit a very popular chord in nations such as England, the United States, and Germany. Indeed, over 30 countries worldwide enthusiastically embraced eugenics, each adopting the movement to fit its own local scientific, cultural, and political climate. It was supported in countries such as Argentina, Cuba, Czechoslovakia, Russia, Brazil, Colombia, Mexico, and Venezuela. Eugenics was seen by many cultures as the truest method to cleanse human society from what were then perceived as hereditary degenerations, such as moral decadence, tuberculosis, chronic unemployment, alcoholism, and a wide variety of social ills.

Scientifically, eugenicists mistakenly believed that most traits, even ones we would describe today as complex traits with multiple loci, were governed by

only one gene. With that being the case, they reasoned, the improvement of human populations would be a matter of controlling which Mendelian “factors” or genes were passed on to successive generations through aggressive selective breeding, to which livestock had been subjected for centuries. According to their thinking, the selective breeding of humans included not only encouragement of larger families within the middle- and upper classes of society in order to propagate their genes of material success and civility but also measures to prevent the reproduction of those individuals deemed unworthy, unfit, or a burden on society. Their solution was enforced sterilization by vasectomy or tubal ligation to people in asylums and convicted criminals. They pushed the idea of sterilization so that those who were sterilized could participate in society without the need for institutionalization, thus deferring the cost to the public.

In America, support for eugenics first became evident around the time of the heated debates between the Mendelians and biometricians. In 1904, Charles Benedict Davenport talked the Carnegie Institute of Washington into funding the creation of the Station for Experimental Evolution at Cold Spring Harbor in Long Island, New York, and in 1906, John Harvey Kellogg created the Race Betterment Foundation in Battle Creek, Michigan. Davenport was to play a major role in the development of eugenics in America.

Davenport, a well-respected scientist, had earned his undergraduate degree in civil engineering and received his PhD in biology in 1892. After short stints teaching at Harvard and the University of Chicago, Davenport arrived at Cold Spring Harbor. While investigating nonhuman breeding and inheritance, Davenport’s lab contributed significantly to basic knowledge of genetic variation, hybridization, and natural selection in animals. However, sometime around 1910, his attention was drawn more and more to human genetics.

Davenport had trained in statistical methods under Galton himself during his graduate studies. This exposure as well as the results of his animal studies set in motion a lifelong devotion to eugenic ideals. Davenport was also an enthusiast of Mendel’s work and applied these principles in humans. He became convinced that through human pedigree analysis, he would be able to predict in accordance with Mendelian principles the occurrence of such traits as feeble-mindedness or criminality as easily as hemophilia or six fingers.

In a classic example of well-intentioned but misinformed science, Davenport established the Eugenics Record Office (ERO) at Cold Spring Harbor with private funding, with himself as director. Harry H. Laughlin was appointed superintendent to take care of administrative affairs. Under Davenport and Laughlin, the ERO collected data on the inheritance of human traits, analyzed census data and population trends, encouraged courses in eugenic principles, and distributed eugenics materials in the United States and Europe.

The popularization of eugenics with the American people now began in earnest. Between 1910 and 1916, articles in periodicals written for the average citizen, such as *Good Housekeeping* and *The Saturday Evening Post*, increased tenfold. Books targeted for public consumption included such works as *The Passing of the Great Race* by Madison Grant (1916) and *The Rising Tide of Color Against White World Supremacy* by Lothrop Stoddard (1920). In 1917, *The Black Stork*, a decidedly prosterilization film, was released for American moviegoers. State fairs entertained and educated Americans through the use of eugenic displays and “Fitter Family” Contests, the first being held at the Kansas Free Fair in 1920. By 1930, eugenics was taught in many high schools. In American colleges and universities, over 350 eugenics courses were offered. Church-going citizens often heard the virtues of eugenics extolled from church pulpits. These efforts succeeded in widespread acceptance of eugenics.

Political action soon followed. As early as 1907, Indiana became the first state to pass an involuntary sterilization law, targeting individuals in mental institutions, criminals involved in more than one sex crime, and those determined to be feeble-minded via IQ tests. By 1935, 26 states had similar laws on the books, and 10 more states were poised to enact such legislation, testifying to the acceptance and popularity of eugenics in American culture. Before the repeal of the last eugenics laws (California, 1979), over 64,000 individuals had been involuntarily sterilized.

The second major arena of eugenics political action concerned immigration. The Johnson Immigration Act of 1924 (Immigration Restriction Act) was the most far-reaching and restrictive immigration act in America to that time. Congress, convinced by the limited evidence presented by Laughlin, voted for severely restricted immigration from “undesirable” nations in Eastern Europe and other countries. According to the evidence, immigrants from such areas possessed lower intelligence than Americans

(determined by English IQ tests given to non-English- or limited-English-speaking immigrants) and a much higher preponderance of negative traits such as alcoholism and insubordination, viewed as heritable traits. Obviously, Congress thought, American society needed protection from such negative effects.

The scientific community did not blindly accept the claims of eugenics. Opposition to the movement grew steadily. By the 1920s, geneticists understood that the traits emphasized by the eugenicists were the result of complex interactions between multiple genes and that no such trait could be attributed to a single gene. Still other research showed that environmental factors greatly influenced the expression of genes. Research also demonstrated mathematically that it would be virtually impossible to eliminate a recessive gene in a population.

Another factor of significance in contributing to America's waning support for eugenics was the Great Depression. This economic calamity turned American society upside down. Suddenly, people in the upper classes of society found themselves with no money and no jobs. More important, they were thoroughly confused. People at this societal level had been taught by eugenics that their genetic traits were virtual guarantees of material success and employment. Finally able to understand that social and economic variables affected social position more than any genetic explanation could, society began to abandon eugenics ideas. When Hitler and the Nazi party came to power in 1933, parallels and connections in eugenics between the United States and Germany were obvious. The embarrassment that America could be associated with the ideals of the Nazi Party resulted in drastic changes to the concept of eugenics in America, to the point that the ERO, which already had changed its name to the Genetics Record Office, closed in 1939.

The rise of eugenics in Germany, viewed by many as the ultimate expression of eugenics, actually paralleled this movement in America. It was introduced in Germany late in the 19th century by physicians and was viewed as the last, best hope for the improvement of the German people, with the focus on increasing national efficiency. Eugenicists in Germany were enthusiastic and supportive of work by Davenport and Laughlin and had read Grant's and Stoddard's books. The progress of eugenics in America in the 1920s fueled Germany's developing optimism that racial hygiene would prevent the total degradation of truly Germanic ideals.

Germany following World War I was a country left feeling hemmed in by enemies and alone in the global community. Early eugenic theories left many Germans, including well-known geneticists, worried that if Germany were not allowed to grow, her "best and brightest" would be forced to migrate from the country, taking their racially pure genes with them and leaving defective ones behind. With the passage of the Johnson Act and sterilization laws, the United States was sending the message to other countries that discrimination and racism were permissible if the ultimate goal was to preserve and promote the purity of human heredity. Later on, this message gave further confidence to the Nazi Party's pursuit of racial cleansing. However, up until the Great Depression and the Nazi takeover in 1933, eugenics in Germany focused on education and social reform.

The Great Depression hit Germany hard. Immediately, the debate intensified as to how to decrease the burden of unproductive individuals on the financial resources of the state. Legislatively, distribution of aid was restructured to support productive or desirable individuals, to the detriment of those viewed as burdens or unproductive citizens. Those deemed feeble-minded, such as individuals with schizophrenia and manic-depressive disorder; those born with disorders such as Down syndrome; and criminals were immediately reduced to near-starvation levels of support. Some have suggested that this devaluing of human life set the stage for the eugenics policies and actions of the Third Reich.

Nowhere was hereditary degeneration and racial impurity more feared or eugenics more accepted and acted upon than in Nazi Germany. By the time that Adolf Hitler rose to power in 1933, the Nazi drive to create a healthy German people, brimming with fit workers, farmers, and soldiers for the Third Reich, had come to a fever pitch. Many medical professionals who firmly believed in the contributions of eugenics to the good of the German people were forced to align themselves with the rabid anti-Semitism of the Nazis. It was with their help that the regime's 1933 compulsory sterilization law came into being. This law directed compulsory sterilization of those diagnosed with schizophrenia, manic-depressive disorder, many genetic disorders, and chronic alcoholism. By 1945, some 400,000 Germans had been forcibly sterilized.

Support for these efforts required a massive public education program consisting of posters, school

textbooks, and documentaries portraying the sterilizations as a humane means to protect the nation from boundless evils. This type of public campaign was used not only to extol the virtues of eugenics programs but also to encourage “good” Germans to produce many more “good” Germans. One of most notorious of these efforts was the Lebensborn project. This project originally encouraged men of the Nazi Schutzstaffel, the SS (which translates as “protection squad”), to produce children with as many willing German women as possible. Medals were handed out to those women who produced four or more children.

On a more ominous note, the Nazi regime first discussed involuntary euthanasia in 1933, but it was not put into place until the commencement of World War II. Hitler believed that the upheaval of the war would diminish public disapproval, and he was apparently correct. It was at this time that Nazi racial hygiene turned from controlling reproduction to “mercy killing” those individuals regarded as genetically inferior. This population of individuals included a wide range of conditions, such as Down syndrome, other birth defects, and elderly psychiatric patients. By the end of the war, nearly 200,000 Germans had been massacred, using such methods as starvation, lethal injection of morphine, and asphyxiation by gas, administered by physicians and nurses. These experiences led the way to the eventual murder of millions of Jews in the concentration camps.

The worldwide backlash against eugenics following World War II drastically diminished public support for the movement. As the horrors of the eugenics policies of the Nazis became known, the name disappeared from the titles of journals and university courses, albeit slowly. For example, one of the authors (Meaney), during his undergraduate training in the early 1960s, enrolled in a course titled “Heredity and Eugenics.” A physician taught the course, and the content was basically what was then known about the genetics of human diseases. Despite these holdovers from the early days, the movement was essentially dead as genetics moved into its next phase.

1953–Present: Molecular Genetics

During this time period, genetics has probably changed the most and experienced its greatest acceleration in terms of discoveries and applications. It started with the discovery of the structure of DNA in 1953.

In the aftermath of World War II and the work of laboratory scientists during the 1930s and 1940s, we were on the brink of understanding the structure of DNA. Following the determination by Oswald and Avery that DNA was likely the genetic material, the race was on to understand this deceptively simple mix of nucleic acids. A group of scientists in the Cavendish Laboratory, at Cambridge University in England, worked diligently to understand how DNA was structured. A sense of academic camaraderie and youthful idealism combined with outright arrogance pushed the work ahead.

One of the young scientists in Cambridge was Rosalind Franklin, who worked in the X-ray diffraction laboratory. Since her arrival at King’s College in Cambridge, she had already demonstrated a critical error in the work of her predecessors. She discovered that there are two forms of DNA in most sample preparations. There is an “A form,” which is more crystalline, and a wetter “B form,” more likely closer to that found in cells. A characteristic X-pattern on the X-ray diffraction screen showed her immediately that the B form was helical in shape.

At this same time, James Watson and Francis Crick, also at Cambridge, began a collaboration to model the structure of DNA. They attempted to solve the structure of DNA as one might put together a puzzle, matching likely pieces in an attempt to produce a coherent picture. In November 1951, Franklin presented the information about the two forms of DNA. Watson was among those who listened. Intrigued by her results, Franklin was soon invited to see the model that Watson and Crick had constructed so far. A brief meeting was held. Apparently, preoccupied with her work, Franklin was quick to discount the model and left as soon as possible. The reaction by their superiors was quick, and Watson and Crick were ordered to abandon their model. But the story did not end here.

The importance of Franklin’s work, in particular the X-pattern on the diffraction screen suggesting the helical structure of DNA, was not lost on Watson and Crick. Forbidden to build models, the structure of DNA nonetheless was never far from their thoughts. Franklin had provided the “Eureka” moment, without her knowledge, when her data were presented. Maurice Wilkins, who worked with Franklin in the X-ray diffraction laboratory, also maintained an interest in the structure of DNA. On numerous occasions, he discussed the subject with his friend Crick. Wilkins was able to obtain one of Franklin’s photos of DNA,

Photo 51, which was an unusually sharp image of the B form of DNA. It made its way to the Cavendish Laboratory, where Watson and Crick perceived themselves to be in the last leg of the DNA race with Linus Pauling. While Pauling had deduced a flawed structure, Watson and Crick knew that with a good X-ray image, Pauling would beat them. Perhaps even more important than the confirmation that the substance was helical, Wilkins had calculated that each turn of the helix contained 10 units per turn, with a spacing of 34 angstroms. Knowing the geometry, it remained to decide how the bases were stacked in the working model.

To beat Pauling to the secret of life, the group still had to publish. The scientists were up against a serious problem. They had no data. Without experimental evidence, they had a nice model but nothing to back it up. A solution was brokered. They would submit three interrelated papers to *Nature*. As it turned out, the three articles were published in a single issue of *Nature* in 1953. The one by Watson and Crick was first, then Wilkins, and finally Franklin and Raymond Gosling, a graduate student who had worked for Franklin. Franklin's work was presented as a confirmation of the model, not as a primary factor in its determination. Within her own previously written paper, she inserted a confirmation of the model, stating that the ideas of Franklin and Gosling were consistent with Watson and Crick's proposed model. Watson and Crick, who acknowledged that their work had been stimulated by the general knowledge of Franklin's research, also referenced Franklin's work.

Adding further significance to the discovery of the structure was research performed by Al Hershey and Martha Chase. Their work finally confirmed that DNA was the heritable substance, an idea still highly contentious even after Avery and Oswald. They were able to show viral DNA was still infective without its protein coats. It was still widely believed that DNA was too simple to be the genetic material and that the best candidates were the more complex proteins.

It almost goes without saying that the discovery of the structure of DNA launched the careers of Watson and Crick. There were still many questions that needed answering, such as how DNA replicated and how were proteins formed from DNA. But these watershed discoveries in the early 1950s were to forever change the landscape of genetics.

In retrospect, Crick's now famous announcement at a local pub that he and Watson had discovered the

secret of life might have been a tad brash. Far from unlocking the mechanism of heredity, they had at this point been able only to describe the appearance of the key. This was a major step, to be sure, but only a step. There remained the question of just how it worked. How does DNA cause the formation of proteins, and how do these proteins assemble into an egg, a hand, a turnip, or an elephant? Key to this question was deciding if the geometry of the DNA molecule directly catalyzed protein assembly or if it carried the directions for other organelles to complete the assembly. Looking at the "recipe," it was obvious that a two-letter code would provide insufficient combinations to produce the required 20 amino acids, and a three-letter code provided an excess of possibilities. There were two solutions published for the mechanism, and both were wrong. Cosmologist George Gamow proposed his "sequence of diamonds" theory, based on overlapping triplets that were responsible for the direct assembly occurring on the surface of the helix. Elegant, as it allowed for the coding of exactly 20 amino acids, it was discounted by Crick because it would not allow for the complex protein sequences that Fredrick Sanger had been describing as he progressed toward the structure of the bovine insulin molecule. Crick preferred the "sequence hypothesis," in which the DNA coded for the remote assembly of proteins. While his hypothesis was correct, his code was flawed. He proposed a code wherein only one variation on a given three-letter codon would code for a single amino acid while other sequences of the same three letters were noncoding, allowing for exact start points. This model also gave precisely 20 amino acids. As perfectly simple and logical as this seemed, it has subsequently been shown that each variation of a triplet has a specific meaning, with several codes being possible for a given amino acid, and allowing for stop codons.

It would not be until the early 1960s that the mechanism for communicating DNA's message through the cell, messenger RNA (mRNA), would become known, providing a better understanding of the code. Ribosomes had already been identified in the 1950s as the site of protein synthesis, and scientists had synthesized RNA. Crick in 1958 described the central dogma of molecular genetics that information flows from DNA to RNA to protein. In 1961, he and Sydney Brenner conclusively demonstrated that the genetic code is a triplet code. Later in the same year, Brenner reported with François Jacob and Matthew Meselson

that mRNA is the molecular structure that carries the message from the nuclear DNA to the cytoplasm, where protein synthesis occurs. By 1965, the codons for all of the 20 amino acids that comprise proteins had been deciphered.

Molecular genetics was not the only area of genetics in which great strides were made during the 1950s and 1960s. Despite the aftermath of World War II and what had occurred in the name of eugenics, new technological breakthroughs in genetics were increasingly applied in human genetics and especially in the study of human diseases. It was not until 1956 that the correct number of chromosomes in a normal human cell was established to be 46. By 1960, methods had been developed to culture blood lymphocytes so that they could be fixed on slides and stained for viewing under the microscope for any abnormalities in chromosome number. These discoveries spawned research into many syndromes, which had been described clinically in earlier years, to investigate the cells of individuals with these conditions to see if there were abnormalities of the chromosomes. Many of the common chromosomal abnormalities, such as trisomy 21 in Down syndrome, were reported during the late 1950s and early 1960s. Cytogenetic techniques were also applied to the study of cancer. In 1960, a specific chromosome known as the “Philadelphia chromosome” was reported to be associated with chronic myeloid leukemia. Later in the 1960s, it was discovered that amniotic fluid could be cultured and the chromosomes in these cells viewed for abnormalities, paving the way for the development of prenatal genetics. Finally, in 1970, it was reported that human chromosomes could be stained through the use of DNA-binding fluorescent dyes to produce unique banding patterns. Thus, more than size and shape could now distinguish human chromosomes. All of these discoveries, in turn, led to the need for more laboratories to do cytogenetic testing and the trained professionals to direct them.

By the late 1950s, grant support was available for the training of physicians to oversee the clinical and laboratory evaluation of patients and the counseling of families. Prior to the developments in human cytogenetics, PhD geneticists provided some genetic counseling, almost exclusively in university-based settings. The training of physicians began a shift toward counseling being provided as part of clinics in which patients were seen and diagnosed, and counseling about the genetic disorder and recurrence risks was

provided for their families. From their origin in the 1950s and 1960s, genetic services have increasingly broadened to include genetic evaluation and testing at all phases of the human life cycle, including prenatal genetics, newborn screening, testing for adult-onset diseases such as cancer, and more.

The 1970s began with much controversy. This stemmed from the publication in 1969 by Arthur Jensen, an educational psychologist at the University of California at Berkeley, of a paper in which he presented data suggesting that racial differences in intelligence, as measured by IQ tests, were primarily due to genetic differences between the populations. Jensen based his argument on data showing that the heritability of IQ in White European populations for which IQ tests were available (i.e., the proportion of variation in IQ scores that is due to genetic variation) was about 80%. Jensen asserted that if heritability of IQ is 80%, this also extended to the difference in average IQ between Blacks and Whites and therefore most of the difference was due to genetic differences between the populations.

Jensen’s work instigated an avalanche of criticism from geneticists, led by the population geneticist, Richard Lewontin. Lewontin published a series of papers in which he explained the concept of heritability and how a within-population estimate of heritability like Jensen used did not explain differences between population, which are due to a combination of both genetic and environmental factors. He went on to investigate whether variation in genetic traits like the human blood groups and proteins is mostly among racial populations or within them. Lewontin’s analyses showed clearly that 85% of the variation for these genetic traits is within and not between populations. Molecular geneticists in the 1990s used DNA markers to replicate Lewontin’s research, and the results were strikingly similar. Therefore, the vast majority of genetic variation overall is within rather than among racial or ethnic populations.

Molecular genetics continued its rapid development during the 1970s. The first restriction endonuclease, an enzyme found in bacteria that can be altered to cut DNA of other organisms at specific recognition sites in the DNA, was isolated. This was a major technological advance in molecular genetics. David Baltimore and Howard Temin made important discoveries for both molecular and cancer genetics in 1970 through their work on RNA-dependent DNA polymerase or, as they called it, “reverse transcriptase,” an enzyme

found in retroviruses that can be used to make DNA from an RNA template (the reverse of the usual transcription of DNA to RNA), and the report of the first oncogene, a gene that is able to change normal cells into cancerous ones. By 1973, the first recombinant DNA (rDNA) molecule, a DNA molecule that is a hybrid of fused sections of DNA from different species, had been reported by Stanley Cohen, Herbert Boyer, and their colleagues. Their publication now is regarded as a marker for the origins of recombinant DNA technology. This new technological advance prompted an international conference in 1975 to establish guidelines for the regulation of its use, due to concerns about the possible contamination of laboratory personnel, the public, and the environment through inadequate safeguards for biological containment.

Many other technological advances that impacted molecular genetics for years to come were made in the 1970s. DNA electrophoresis, a method used to separate DNA molecules, usually in a gel, by their electrical charge, shape, and size, was improved. The Southern (Edward M. Southern) blot, a method by which single strands of DNA are separated in a gel and transferred to a special filter in which radioactive probes are placed to identify specific DNA segments, was developed. Also, the first complementary DNA (cDNA) cloning was demonstrated. This depended on the method of reverse transcriptase and is a method of making multiple replicas of segments of DNA through reverse transcription, that is, using mRNA to make the DNA segments. By the late 1970s, several laboratories were developing methods for sequencing DNA. Frederick Sanger and his colleagues reported in 1977 a method of DNA sequencing that had a major impact on the research leading to efforts such as the Human Genome Project. Sanger and his group used the technique in a bacteriophage to produce the first fully sequenced genome. In the same year Boyer and Robert Swanson founded the first biotechnology company, Genentech. Genentech innovated the use of recombinant DNA technology to establish many pharmaceuticals of use in the treatment of human diseases, including Somatostatin, the first human protein produced through biotechnology. In 1978, scientists at Genentech cloned the human insulin gene, paving the way for the substance to be produced through rDNA technology. This happened in 1982, changing the treatment of diabetes from the use of nonhuman insulin to treatment using

the biotechnology-derived insulin. One could see already that the impact of molecular genetics on medicine was going to be immense.

During the 1980s and 1990s and into the new millennium, genetics has continued to develop at an increasingly accelerated pace. The 1980s was a period of tremendous technological advances in molecular genetics and also in the application of this technology across all areas of genetics. Recombinant DNA technology continued to develop and be applied in such diverse pursuits as the improvement of industrial microbes, genetic engineering of plants, and the diagnosis of human diseases. Biotechnology companies were having major successes in the cloning of genes, which provided a stimulus for investments from the private sector. The DNA-sequencing technology that originated in the 1970s was advanced significantly through improvements in instrumentation to increase sequencing capacity. The United States and other governments worked to increase fiscal support for these efforts, with an eye toward a future that was to include the Human Genome Project and sequencing of diverse animal and plant genomes.

Many other technological innovations had their origins in the 1980s. Polymerase chain reaction (PCR), a method used to amplify specific DNA sequences rapidly from small amounts of double-stranded DNA, was developed by Kary Mullis and his colleagues. Today, PCR is not only used in genetics, but in all of the biological sciences and medicine. Its application made possible the rapid development of DNA markers for multiple uses and many diagnostic methods for human diseases. The development of restriction fragment length polymorphisms (RFLPs), varying lengths of DNA fragments resulting from the recognition by restriction enzymes of differences in the base pair sequence (mutations), and the application of this methodology, was another major breakthrough. David Botstein and his coworkers had proposed in 1980 the means of mapping the full human genome based on this technology, and it was soon being used as a marker or indicator of the chromosome location of specific genetic diseases. The first genetic disease to be mapped in this manner was Huntington's disease in 1984, when it was reported to be located on Chromosome 4. Instances of disease genes so identified rapidly multiplied. In 1987, the yeast artificial chromosome (YAC) technology, the use of synthesized chromosomes to make gene libraries and transfer genes among species, was reported. This

method, with other advances, allowed scientists to construct libraries of genomic DNA, a resource of significant application for any of the emerging genome projects. Another technological innovation of the 1980s was transgenic technology in both plants and animals. This technology allowed scientists to produce organisms into which genes from other species had been transferred and incorporated into the germ line of the new organism. Its use has been in transferring human disease genes into organisms such as mice (transgenic mice) in order to study the effects in mice with the ultimate aim of developing effective treatments.

Although the innovations of molecular genetics probably garnered the most headlines during the 1980s, there were many substantive developments in the use of genetics knowledge. In the United States, a federal bill and appropriation of funds led to the expansion of genetics services across the states, beginning in the mid-1970s, to ensure their availability in all sectors of the population. Although there were significant cutbacks in these funds during the early 1980s, clinical and laboratory services for genetic diseases continued to expand, as new genetic tests became available and other sources of support were tapped. The 1980s saw the first real attention paid to the quality of these services through the formation of public-health-funded, multistate networks to ensure that both laboratory and clinical services met a peer-determined standard of quality. Relevant to anthropology, there were public-health-funded projects starting in the late 1980s and continuing into the 1990s to improve the cultural competence of the delivery of genetic services. Finally, the 1980s produced an expansion of genetics support groups for individuals with genetic diseases and their families and a rapid expansion in the availability of genetics information, which was only the bare beginning of what was to come in the 1990s.

The Human Genome Project (HGP) was by far the most significant accomplishment in the 1990s. It began as a controversial proposal by the U.S. Department of Energy. Skepticism was deeply rooted. The project was initially viewed as technologically impossible and was likely to consume vast amounts of dollars to implement. The strong support from the National Academy of Sciences and U.S. Congress made it possible for the HGP to be initiated in the United States in 1990 by the National Institutes of Health (NIH) and Department of Energy. During the early part of

the decade, the HGP converged with similar efforts in other nations to become an international investment.

The HGP officially kicked off in October 1990, with a budget of \$60 million. Its primary goal was to determine the entire sequence of the 3 billion chemical bases in the DNA that comprises our genome, or, as some have put it, to uncover the “instruction manual” for *Homo sapiens*. James Watson was chosen to lead the project. He swiftly made a number of decisions concerning the goals of the HGP. One involved devoting 5% of the budget toward the study of ethical, legal, and social implications. Watson, among others, viewed this as extremely important considering the many issues concerning genetic discrimination, inadequate treatment options, and eugenics.

Watson, belabored by a series of conflicts and controversies for which his personality was probably ill-suited, stepped down from the directorship of the HGP in April 1992. Francis Collins, an accomplished and well-respected medical geneticist from the University of Michigan, was recruited to replace Watson. Collins provided the leadership for the HGP to reach its broad objectives, which included development of genetic and physical maps of the human genome and mapping and sequencing of simpler model organisms, such as bacteria, yeast, roundworm, and the fruit fly.

While Collins continued his work on the HGP, Craig Venter, a scientist who had been at the NIH during Watson's tenure, was about to engage in DNA sequencing and potential gene patenting. After his resignation from the NIH in July 1992, Venter set out to create the world's largest DNA sequencer, the TIGR. Venter, who headed a new company known as Celera Genomics, was applauded for his efforts to sequence the genome privately, because it would simply speed up the generation of the human sequence. At that point, only 4% of the genome sequence was complete. The U.S. House of Representatives Subcommittee on Energy and the Environment had a meeting to discuss the implications of Venter's entry into the human-genome-sequencing activities. Both Venter and Collins addressed Congress concerning genome sequencing. In his testimony, Collins stressed the importance of meeting the standards that had been developed by the international community of human genome scientists. The race to unlock the human DNA continued. Collins and Venter eventually would merge to complete the HGP, and on June 26, 2000, they announced in the White House with President Bill Clinton that the rough draft of the HGP was complete.

During the 1990s and into the new millennium, numerous other developments occurred. In 1990, the first attempt at human gene therapy took place, involving a child with an immune system disorder. In 1994, the highly publicized book *The Bell Curve*, by Richard Herrnstein and Charles Murray, was published. The book discussed the relationship between IQ and ethnic groups and was a throwback to the controversies 25 years earlier as a result of Jensen's article on race and IQ. It certainly produced a similar level of outcry by scientists and the public alike, mostly in response to the strong tones of genetic determinism and Social Darwinism. By 1994, genes that predispose individuals to disease were being identified, including the Ob gene, which predisposes individuals to obesity, and the breast cancer genes. In 1995, the sequence-tagged site (STS) gene-mapping technology was developed. This is a method by which short sections of cloned DNA (100–200 bases in length) are randomly selected and sequenced to mark the larger DNA sections in which they are found. It effectively speeded up the work of the HGP. A year later, a look at public interest in genetics took place through a national survey. It was found, not unsurprisingly, that the public viewed genetics with fear and mistrust. More fuel for public misgivings was loaded in 1997, when Scottish scientists cloned a sheep named “Dolly.” Barely a year later, reports by teams of researchers working with embryonic stem cells added to public concerns. The same year, the draft of the human genome map demonstrated the locations of more than 30,000 genes. The complete map of the human genome was published ahead of schedule, 3 years later.

Completion of the human genome sequence is a major milestone for biology, health, and society. However, the role of genetic information for disease prediction and prevention has been viewed with uncertainty. This uncertainty is expressed in one sense by the number of DNA variants that are apt to be linked to such diseases as cancer, cardiovascular disease, and other complex diseases. In addition, early detection is an issue because there is uncertainty about the risk conferred. The patterns of transmission for developing a certain illness are not always predictable and in the case of many common adult-onset diseases are dependent on environmental effects, including social, economic, and other environmental exposures. Information about susceptibility to all diseases is certain to improve and therefore people in the future will have the ability to take steps to reduce their risks.

Interventions such as ongoing medical assessments, lifestyle modifications, and diet or drug therapy will be offered to those at risk. For example, through a genetic test to identify people at risk for colon cancer, individuals receive regular screening of the colon that could help in preventing premature deaths. Another area of concern in this regard is the availability of drug therapy and interventions for genetic diagnosis for those who already have a major problem with access to health care. This may very well create another category of discrimination with respect to services for genetic diseases.

Genetics has entered the era of genomics and bioinformatics as a result of the sequencing work on a number of plant and animal genomes and the virtual explosion of databases and comparative information produced by these respective technologies. The convergence of molecular genetics with computer technology has produced a staggering amount of information for any single human being to comprehend. What we do know is that cracking the human and other genomes is just the beginning in our quest for a more complete understanding of genetics. The next challenges will be to understand how the genomes direct and coordinate the development of plants and animals, including humans, and how the environment is involved in developmental processes. Then, the ultimate challenge will be how to use the immense knowledge base of genetics to improve our lot, at the same time protecting the only planet we currently inhabit and its diverse biology.

GENETICS, HUMAN

Human genetics is the study of the inheritance of epigenetic traits among humans, notably but not exclusively traits of medical interest. The overarching goal of human genetics is to apply knowledge of human heredity to a better understanding of diversity in development and adaptation as “nature is nurtured.” Another central goal of human genetics is the public health function of reducing dysgenetic burdens on individuals, families, and society at large. Although the boundaries of subdisciplines within genetics are not precise, the term *anthropological genetics* is used to distinguish general human genetics from more clinical applications, with the latter sometimes denoted specifically as *medical genetics*.

Humans, like all species, have many genotypic and phenotypic variations. Such variation is ultimately derived from mutations that affect proteomic expression. Genes encode for proteins that ultimately arrange and regulate all manner of biological structures and processes, from the intracellular level to organismic and even on the ecological. Thus, mutant genes disrupt proper proteomics processes, and disease results to the extent such disruptions are evident as defects (pathophenotypes). Many mutations have no pathological effect, but there are more than 6,000 known single-gene disorders, or about 1 of every 200 live births. Moreover, there may be manifold causes of phenotypically similar disease; for example, some 60 congenital forms of deafness are known, with some the result of environmental factors such as rubella and others due to genetic mutations. Genetic disorders, as caused by abnormalities in genetic material, occur in four basic types: (1) single-gene, (2) chromosomal, (3) multifactorial, and (4) mitochondrial.

1. Single-gene (Mendelian or monogenic) defects are due to mutations of DNA at a single locus. Single-gene diseases arise in the classic familial patterns of inheritance: autosomal dominant, autosomal recessive, and X-linked. Major examples of such Mendelian diseases include cystic fibrosis, sickle cell anemia, Huntington's disease, phenylketonuria, alpha-1-antitrypsin deficiency, and hereditary hemochromatosis.

2. Chromosomal defects are due to abnormalities such as allelic deletions or redundancies; translocations of or even gross are evident on microscopic examination. Down's syndrome (trisomy 21) is a common disorder that occurs with a redundant portion of chromosome 21.

3. Multifactorial (complex or polygenic) defects are due to interactions of multiple alleles and the developmental environment. Many of the most common illnesses are multifactorial, including arthritis, cancer, diabetes, heart disease, and hypertension. Given such complexities of expression, multifactorial inheritance is more challenging to study.

4. Mitochondrial defects are due to mutations in mitochondrial DNA, which is distinct from the inherited nuclear-chromosomal genotype of the organism. Since mitochondria are the small organelles of cellular respiration in the cytoplasm of plant and animal cells, such anomalies can cause a variety of specific metabolic diseases.

Medical genetics historically developed in practical application for medical screening and advice for at-risk populations. Such screening requires not only adequate tests (valid, reliable, sensitive, specific) but also a sound grasp of the natural progression of and treatment options for the disease in question. A thorough family history augmented with a review of pertinent medical literature, preferably by an expert, is essential to inform families of the diagnosis and methods; identification of carriers; the phenomenology of the disorder, including complications; risk of recurrence for the patient and family; and therapeutic and reproductive options, including referral or support groups. This is a complex process of evaluation and education and carries considerable legal and ethic consequences.

Heterozygote screening is focused on susceptible populations with high rates of deleterious heterozygosity (for example, cystic fibrosis in Scandinavians,

Tay-Sachs in Ashkenazi Jews, sickle cell anemia in Blacks, etc.). Prospective screening of parents, particularly where one is an identified heterozygote, allows more informed medical choices. Pre-symptomatic screening may be helpful within families with a history of Mendelian disorders. Such screening is most typical in certain dominant traits (for example, Huntington's disease) but can be very useful in other types of familial disease risk (for example, cancers of the breast and colon).

Medical genetics also entails other clinical procedures, such as *prenatal diagnosis* (sampling of chorionic villus tissue, umbilical cord blood, maternal blood sampling, or maternal serum, as well as fetal imaging via ultrasound or radiography). Prenatal screening is especially useful for prospective mothers over age 35 with family history of a condition diagnosed by prenatal tests, to evaluate abnormal maternal serum screening or some complications of pregnancy. Likewise, *neonatal screening* may be used to identify newborns in need of critical special treatments (special diets for phenylketonuria or replacement therapy for hypothyroidism).

Pedigree analysis is a classical technique of medical genetics by which a thorough family tree is depicted, with symbols for persons affected with known genetic disease. Thus is rendered a broad summary of inheritance patterns through generations that serves to clarify mode of transmission even for traits that may have identical phenotypes despite different causal genes (for example, cleft palate can be Mendelian autosomal dominant, autosomal recessive, or X-linked recessive; other types are multifactorial as they run in families without clear patterns).

However, with this progress, an increasing number of gene tests are becoming available commercially, although the scientific community continues to debate the best way to deliver them to the public and medical communities, who are often unaware of their scientific and social implications. While some of these tests have greatly improved and even saved lives, scientists remain unsure of how to interpret many of

Source: © iStockphoto/Bertrand Collet.

them. Also, patients taking the tests face significant risks of jeopardizing their employment or insurance status. And because genetic information is shared, these risks can extend beyond them to their family members as well.

As the role of genetics is made clearer with respect to diagnosis, monitoring, and treatment of diseases, medical scientists continue to make rapid progress in the identification of genes associated with disease. A key long-range aim is to formulate new means to diagnose, treat, and even cure or prevent diseases. Epigenesis is a complex process that entails regulators (i.e., promoters and enhancers), actively expressed units (exons), unexpressed but intervening units (introns), and termination signals.

The field of human genetics has been dramatically bolstered by the Human Genome Project (HGP) and related studies that began in 1991. These constitute the new field of genomics that use techniques of molecular analysis to map all human genes to specific locations and thereby identify elements of genetic structures and functions. With this progress, medical genetics is expanding from a focus on diagnostics and counseling toward more active evaluation and treatment, including the prospect for procedures to directly repair dysgenetic cell lines. Similarly, human genetics has also progressed rapidly toward the elucidation of diverse issues in the phylogenetic history and geography of human populations.

**PRIMATE GENETICS**

Scientists hope to find cures for many human diseases through the study of primate genetics. Eight National Primate Research Centers (NPRCs) are located across the United States. These centers are closely affiliated with academic institutions. The rationale is that primates are closely related to humans in their molecular, immunological, reproductive, and neurological characteristics. Therefore, they seem to be the ideal surrogates to stand in for humans in this sort of testing.

Over 20,000 nonhuman primates are maintained by the NPRCs across the country, the majority of which are macaques. Investigators who receive research funding from the National Institutes of Health may use these centers, but they also are open to scientists who are funded by other agencies, research foundations, or private funds. Many research projects involving primate genetics are occurring in other places, too. At Stanford University, tests with primates have shown that a pill developed by Pfizer may stop transplant rejection. It works in monkeys that have undergone kidney transplant, and scientists hope that facility carries over to humans.

The Tulane National Primate Research Center is studying the ability of some monkey species to resist developing AIDS. A \$2 million, 5-year grant is funding the study. Scientists hope to determine how the African green monkeys can resist developing AIDS when infected with SIV, the monkey equivalent of HIV.

A Wisconsin team of molecular geneticists is working on a contract for characterizing nonhuman primates to enhance transplant biologists' work worldwide. The 5-year contract is from the National Institute of Allergy and Infectious Diseases. The team will be working with rhesus and cynomolgus monkeys.

The California Regional Primate Research Center is working to determine the toxic effects of certain agents that are likely to cause embryonic abnormalities. The Oregon Regional Primate Research Center is researching degenerative diseases. At the Southwest Regional Primate Research Center in San Antonio, TX, scientists are researching genetic bases for susceptibility to hypertension, osteoporosis, obesity, and infectious diseases. Research at the Caribbean Primate Research Center in Puerto Rico includes using primates to study such diseases as macular degeneration, glaucoma, and diabetes. These are but a few examples of the types of genetic research being done with primates.

**TWIN STUDIES**

Because monozygotic or identical twins have identical genes, they have been widely employed in medical and psychological research. The twin method compares sets of monozygotic twins to control sets of dizygotic or fraternal twins who have been raised in the same family environment to examine the relative importance of heredity over the environment in the development of certain diseases, in the formation of the personality and sexual orientation, and in intelligence. Through twin studies, researchers have, for example, demonstrated a strong genetic component in the development of schizophrenia, alcoholism, depression, obesity, and in the inclination to infectious diseases such as tuberculosis.

The 19th-century behaviorist Sir Francis Galton first noted in 1875 that "twins have a special claim upon our attention" because "their history affords means of distinguishing between the effects of tendencies received at birth, and those that were imposed by the special circumstances of their after lives." Since Galton's conclusion, twin studies have been a powerful if problematic tool in the hand of geneticists. Classical twin studies claim that any excess likeness in a given trait between identical

twins when compared to fraternal twins, who only share 50% of the genes, should be due to genes rather than environment.

More contemporary twin studies have also tried to establish the extent of the impact of a person's common surroundings (such as the family) and unique events in one's life on a trait. A founding assumption of twin studies is random mating, the idea that people are as likely to choose partners who are different from themselves as they are to choose partners who are similar for a particular trait. Otherwise, fraternal twins could share more than 50% of their genes. A second important hypothesis of twin studies is the argument that fraternal and identical twins raised in the same homes experience equally similar environments.

Twin studies have had to face numerous challenges. Some researchers have concluded that people are more likely to select mates with similar levels of intelligence, making the application of the discipline to the study of intelligence particularly problematic. In addition, twin studies do not acknowledge the possible interactions between genes and environments, but tend to consider their influence on a trait separately. Twin studies, however, have also been capable of taking into account several objections and improving research methodologies, which have expanded to include examinations of twins' extended families, longitudinal studies, and other variations. In the age of genomes and molecular genetics, the future of twin research seems to depend on its ability to combine its traditional methodologies with molecular genetics research.

— Luca Prono

GENETICS, POPULATION

Population genetics is the study of the inheritance, distribution, and fluctuation of allele frequencies as affected by the four main forces of evolutionary genomics: natural selection, mutation, genetic drift, and migration. Population genetics is the overarching discipline of which quantitative genetics is a crucial subfield that calculates selective effects. Ecological

genetics is another subfield that closely examines gene-environment interactions, particularly in wild populations. Molecular genetics deals with the structure and function of genes at a molecular level. Thus, quantitative and ecological genetics are cognate areas of population genetics, and taken together, they all extend classical genetics in unique ways.

Genetic variation is typically cited as the ultimate fuel of evolution, but as organisms adapt in constantly changing environs, it is more precisely *allelic* variation upon which operate the forces of evolution. Alleles are variations of the same genetic loci that can express different phenotypes. Novel alleles arise in genomic populations via random mutation, and the frequency of occurrence of an allele changes regularly as a result of mutation, genetic drift, and selection. Such study of genetic frequency is relevant to a wide range of issues to do with diploid genomic populations. All diploid organisms have two elements—one allele inherited from each parent—at each genetic locus. Where these two elements are different, the organism is said to be heterozygous. Mendelian principles allowed early population geneticists to study heritable form of allelic traits, that is, the genotype, with an emphasis on the observable phenotype: the outward, expressed traits or physical manifestation of specific genetic loci, including variant alleles and heterozygotes.

Meanwhile, in 1908, the mathematical foundation of population genetics was independently discovered by the British mathematician G. A. Hardy and a German physician, W. Weinberg. The Hardy-Weinberg formula establishes parameters by which to predict expected genotypic frequencies of alleles in diploid populations. In a large, randomly breeding population, intergenerational allelic frequencies do not change in the absence of unbalanced mutation, gene migration, selection, or genetic drift. This equilibrium is a mathematically simple expression (for example, $p^2 + 2pq + q^2 = 1$). Thus can be calculated how alleles evolve in serial generations to the extent that they vary from equilibrium parameters.

Variations of allelic frequency are quantified with respect to demographic adjustments of population structures in evolutionary environmental space and time. Hence, population genetics is the systematic elucidation of essential biological phenomena, such as adaptation and speciation—with *adaptation* here meaning enhanced reproductive success of a given anatomical, physiological, or behavioral feature evident by increased allelic frequency over successive

generations and *speciation* meaning the appearance of qualitatively novel species of organism. A key premise of population genetics is that inheritance of both quantitative and qualitative traits are based on similar natural laws.

Population genetics is the main technique derived from the so-called modern evolutionary synthesis of the early 20th century, which melded neo-Darwinism with the rediscovery of Mendel's elegant laws of genetics. It is neo-Darwinian in that Darwin could not have known the precise basis of biological inheritance as the mechanism of genetics. As a consequence, Darwin never fully rejected the Lamarckian notion of acquired-but-heritable traits. However, his intellectual heir, George John Romanes, dismissed such Lamarckian ideas and termed evolutionary mechanisms that were necessary, sufficient, and yet entirely epigenetic neo-Darwinism.

Yet only with the rediscovery of Mendelian genetics in 1900 was a neo-Darwinian evolutionary science made more complete and rigorous. Still, it was not yet immediately clear on what variations processes of natural selection operated most directly. A biometric approach was formulated by the pioneer statistician Karl Pearson, who also widely influenced modern medicine, epidemiology, and anthropology. Pearson focused study on the importance of subtle heritable differences as the basis of Darwinian evolution. A countervailing view was the Mendelian school formulated chiefly by William Bateson. Bateson thought Mendel's work indicated that more abrupt, large-scale differences were the major mechanism by which evolution progressed.

This conundrum was finally resolved in 1918 by the remarkable geneticist-statistician, Sir Ronald Fisher. Fisher's paper *The Correlation Between Relatives on the Supposition of Mendelian Inheritance* invoked a continuous variation model that could derive from diverse discrete loci. Other central figures who, from this starting point, helped propound the modern synthesis include Theodosius Dobzhansky, J. B. S. Haldane, Sewall Wright, Julian Huxley, George Gaylord Simpson, and Ernst Mayr. Clearly, the signal achievement of the modern synthesis is how it not only joined Mendelian and Darwinian perspectives on evolution but also placed the synthesis within a robust mathematical framework.

Among Dobzhansky's many contributions, he operationally defined evolution as being "a change in the frequency of an allele in a gene pool" and also famously averred that "nothing in biology makes sense except in

light of evolution." For his part, Haldane firmly reasserted the primacy of natural selection as mathematically compatible with Mendelian genetics. Wright identified the importance of genetic drift in the course of evolution. Huxley, much like his grandfather T. H. Huxley, helped popularize evolution for a broader audience. Simpson, given his expertise as a paleontologist, introduced important considerations that enriched and leavened sometimes weighted mathematical reductionism of the modern synthesis. Mayr, a superb field biologist and trained physician, contributed in many ways, but perhaps particularly with his naturalist's understanding of the importance of mating schemes and population isolates.

Other imminent population geneticists of the mid-to late 20th century include Motoo Kimura, Richard Lewontin, Luigi Cavalli-Sforza, John Maynard-Smith, William Hamilton, and George Williams. Kimura, with innovative diffusion equations, calculated probability and time to fixation of alleles, whether adaptive, deleterious, or the heretofore underappreciated but very important neutral trait. Lewontin was a pioneer in molecular studies of evolution. Cavalli-Sforza, a research physician among the first to study how modern genomes constitute an "archeological" record of inheritance and prehistory, greatly systematized the genetical study of demography in a manner free of the racist bias that constrained earlier eugenics. Maynard-Smith educed remarkable genetic and evolutionary psychological insights as he infused population genetics with game-theoretical mathematics. Hamilton published in zoology and genetics, including his theoretical analyses that established a rigorous genetic basis for the existence of kin selection, now among the most widely cited papers in all of science. Williams promoted a genocentric view that has taken Darwinian ideas in new directions.

Beyond the modern synthesis, more recent advances in biochemical techniques have fostered the study of single genes (or other markers) at the molecular level. Whatever may be the methods used to identify genes and their alleles, either qualitatively or quantitatively, population genetics relies on statistical analyses of allele frequencies to understand and make predictions about gene flow in populations past, present, and future.

HUMAN DIVERSITY

Human beings are found almost everywhere in the world in a very rich variety of physical types and cultures. People vary physically to an enormous degree in height, hair color, skin color, weight, strength, mental capacity, and more.

Individual human diversity is due to personal genetic makeup. Viewed as groups of people who have transmitted their genes to succeeding generations, human diversity is due to both biology (genotype) and to cultural features of the environment (phenotype).

The phenotype is the outward manifestation of physical human features. Phenotype is everything that is physical, such as metabolism, reflexes, tissues, bone structures, and other body features. Anthropologists have theorized that the enormous diversity among humans is due to natural selection. Genotype is a product of human evolution.

Some attempts to explain human diversity have focused on environmental factors. For example, height aids in purging body heat in hot climates; stocky body structure conserves body heat in cold climates. Light skin color allows vitamin D to be absorbed more readily in cloudy northern climates, while darker skin is less prone to skin cancer. The effect in terms of evolution is that in each environment, some physical traits are more adaptable than other traits.

Humans vary in biology, but they also vary in their way of life. The overall culture of each region or each people is similar because generally, all people eat, sleep, marry, have children, work, and die. However, the practices that direct a particular culture are adapted to respective environments. Some researchers believe that cultural practices or sheer physical isolation can inhibit genetic variation and thus inhibit the evolution of humans.

The Human Genome Project was an international project that sequenced and mapped human genes in order to understand the diversity and unity of the entire human species, *Homo sapiens*. It was completed in April 2003.

The Human Genome Diversity Project is like the Human Genome Project. It is an international effort by anthropologists, geneticists, doctors, linguists, and other scholars. They are working to document the global genetic variation of the Earth's peoples. The Human Genome Diversity Project is seeking to understand why there is such enormous diversity in the people of the Earth, all of whom are widely believed to be ultimately related. However, this relation has been denied by some, which, if true, would have numerous implications for theories about race differences.

— Andrew J. Waskey

GENOCIDE

The term *genocide* is derived from the ancient Greek word *genos* (meaning a tribe or race) and the Latin *cide* (killing). Raphael Lemkin first used this term in 1944. Lemkin worked for the creation of international standards intending to outlaw the wanton and directed killing of identified peoples. Ultimately, Lemkin's efforts were the driving force in the formation of the United Nations Convention Against Genocide.

Genocide is narrowly defined as a society or nation turning against a subgroup that is seen as an internal enemy. Helen Fein provides a broader and far more accurate understanding. She maintains that "Genocide is the calculated murder of a segment or a group

defined outside the universe of obligation of the perpetrator by a government, elite, staff or crowd representing the perpetrator in response to a crisis or opportunity perceived to be caused by or impeded by the victim.” This expanded definition includes the occasion of one nation conducting a war of annihilation against another.

Acts of genocide share a common trait that also serves as a justifying mind-set for acts of extermination: The cultural or economic environment of the aggressive entity or nation must have reached a specific state where genocide is accepted and even embraced as necessary. Staub asserts that changes or shifts in life conditions within certain cultures (bearing distinct characteristics) may generate the necessary social/psychological reaction. He states, “Sometimes a whole society or substantial and potentially influential segments of society face serious problems that have a powerful impact and result in powerful motivations” (Staub, 1989, p. 13). The force exerted by change varies by the magnitude, degree, and intensity of the influencing condition.

Perhaps the most important condition conducive to a genocidal action is the rigidity or the inability of the aggressor culture to adapt. A society with inflexible values and ways of life is likely to be more affected by change. Rigidity makes the difficulties of life more stressful. Consequently, members of a culture are more easily accepting of radical solutions and the placement of blame for their immediate crisis, with the expended slaughter of a targeted population as the necessary solution.

Fein identified four distinct categories of genocide. *Developmental genocide* serves to remove the indigenous members of an area for the purpose of geographic expansion. *Despotic genocide* is a means of removing political opposition in the course of power acquisition. *Retributive genocide* addresses ethnic and similar social stratifications conflicts over power and dominance. *Ideological genocide* is grounded upon the intolerance of contrasting belief systems and the perceived inability to coexist.

The earliest known history of genocide is chronicled in the Old Testament, where reference is made to complete annihilation of the Amalekites. The most notable example of early genocide is the Roman destruction of Carthage, in 146 BC. One historically acknowledged act of complete genocide took place in 1806, when the British began the annihilation of the Tasmanian aborigines, allegedly over the spearing of

livestock. By 1835, the few remaining Tasmanian were resettled on barren Flinders Island. The last full-blooded Tasmanian died in 1876. Acts of genocide have taken place throughout history, with numerous examples taking place during the 20th century. During World War I, the Turkish government planned and ordered the massive murder of Armenians within their borders. In World War II, Hitler ordered the systematic gathering and killing of Jews and other “undesirables” across Europe, in what was to be known as the Holocaust. In 1975, the communist Khmer Rouge exacted victory in the civil war in Cambodia. After assuming control of the country, they began a period of forced slavery, torture, and killing in which over 2 million persons lost their lives. In 1976, over 9,000 persons “disappeared” in Argentina in a wave of military actions following a coup.

Simply defined, *genomics* is the study of an organism's set of genes and their functions. An organism's genome could be considered its instruction manual, and genomics is the science of reading and interpreting that set of instructions. The information contained within an organism's genome controls every aspect of its life, including growth, maintenance, and development, and for humans, it includes instructions on behavior, physiology, and susceptibility to

some diseases. This is not to say that the environment does not count. We are only beginning to unravel the complexities of the interplay among genes and environmental exposures involved in growth and development and the occurrence of disease. On the genetics side, genomic scientists analyze the function of genes within an organism to determine how the genes determine or influence phenotypic outcomes. The study of human genomics will be applied in areas of research such as biological evolution, human migration, molecular medicine, and a vast array of other disciplines.

The field of genomics encompasses many areas of science, because it involves the smallest building block of life, DNA. Genes contain DNA, chromosomes contain genes, and genomes are comprised of all these levels of genetic structure. Almost every cell within an organism contains its unique genome. Genomes can be categorized by individual and by species. Each species has a unique genome, and every individual or organism within that species has certain derivations of that genome. Genomes of individuals within a species are similar enough that it is only necessary to study one or a few genomes to glean information for the population.

Some question why it is necessary to know the entire sequence of a genome instead of simply determining the sequence of individual genes. Not every gene is recognizable. Knowing the full sequence of a genome will help scientists determine what sequence is an actual gene and also allow them to examine how the whole genome works and how genes work together. In addition, knowledge of the entire genome sequence will help scientists study those areas that do not code for proteins in order to determine their importance and function.

Now that the Human Genome Project has published the full sequence of the human genome, scientists will begin to examine the variations among species closely and distantly related to humans. Studying the genomes of organisms distantly related to humans will provide information on species evolution. Sequencing and examining the genomes that are closely related to human, like that of the chimpanzee, with which we share 98.8% identity, could tell scientists exactly why we are different. Comparing the two genomes may show why the physical and mental development of humans is so much more advanced than that of chimps.

Along with studying the variation between species, the differences in the genomes of humans will be a

tremendous tool for medical genetics, forensic anthropology, agriculture, and many more disciplines. For molecular anthropologists, genomes contain the history of the human species. Genomic studies can provide historical information on the migration and mating patterns of human populations. Genomics is also a tool for molecular geneticists studying human diseases and complex traits like personality. Scientists believe that slight variations between human genomes can make one individual have a higher or lower risk for heart disease, different forms of cancer, or Alzheimer's disease. Genomics will be an invaluable tool for all of science in the years to come. One can only hope that the real benefits of genomics for humankind will outweigh the effects this advancing knowledge is bound to have in terms of ethical issues, such as who will have access to its application in medicine and to the information derived there from.

GEOLOGIC COLUMN

The term *geologic column* brings to mind rock layers, laid one on top of another, representing the geologic history of the Earth. However, this picture is only a small part of what constitutes the geologic column. In no place on Earth do preserved sediments represent the entire geologic column; sediments representing significant portions of geologic time are missing in all localities. The complete column would be an estimated 360 km (200 miles) thick, and the Earth's crust is only about 70 km (39 miles) thick.

Source: © iStockphoto/Paige Foster.

The geologic column is best described as a project that has gone from simple, local correlations to an ongoing correlation of all rocks on Earth by their age. This postulated column has been created through comparison and correlation of individual strata from around the world made by thousands of researchers over the last few hundred years. It has traditionally been based on the concept of relative time—this stratum is older than that one but younger than this one. Recently, however, radiometric dates have been used to reconcile the relative dates with real time. Understanding the geologic column thus requires an understanding of the project itself and the history of its creation.

It must first be noted that two closely related concepts, the geologic column and the geologic timescale, are actually separate entities. The geologic column is composed of strata with reference to their relative positions based on time correlations, while the geologic timescale is a time chart tied to various rock formations around the world. The distinction is small but significant. The commonly used terms of *era*, *period*, *epoch*, and *age* are chronologic units of the geologic timescale. Equivalent terms of the geologic column are *erathem*, *system*, *series*, and *stage*. The

geologic column was the original project of geologists, while the geologic timescale became important only after the discovery of radiometric dating techniques.

The attempt to understand the geologic column undoubtedly started when the first human seriously pondered the origin of observed rock sequences. Early researchers, including Pythagoras, Xenophanes, Thales, and Aristotle, contemplated the origin of the Earth's rocks and fossils in terms of natural causes. However, this concept was soon all but forgotten. The Judeo-Christian religious movement, with its “young Earth” interpretations, provided the dominant influence for nearly 2,000 years. During that time, the possibility of an “old Earth” was unthinkable (or at least unmentionable). This belief attributes virtually all the Earth's sedimentary layering to a single flood event and suggests a static Earth created in its current state. This concept went virtually unchallenged, and it was the mid-1500s before anyone again seriously questioned the origin and age of the Earth's rock formations.

Leonardo da Vinci was one of the first persons in recent history to actually research and write about the origins of sediments, but he wrote in mirror writing and kept his notes in his personal possession lest the

Church would find in them cause for persecution. It wasn't until the 1800s, when his notes were deciphered, that the extent of his research on the geologic column was known. However, rumors of da Vinci's research, along with his own observations and curiosity, sparked the interest of Nicholas Steno, a brilliant anatomist and the first recorded "geologist" of modern times. His 40-page publication, "Preliminary Discourse to a Dissertation on a Solid Body Contained Within a Solid," is the first modern publication on the topic of geology and proposes the concept of older layers of sediment occurring below younger layers, later called the *theory of superposition*. Among other concepts put forth in the paper, he also suggested that sediments were generally laid down in horizontal layers. This later came to be known as the *theory of original horizontality*. Unfortunately, his work received widespread criticism, and the dissertation promised in the title of this revolutionary work was never finished.

It is well-known that this preliminary work was the inspiration for many workers over the next century, including Robert Hooke, Abraham Werner, Giovanni Arduino, and James Hutton. Arduino's work is presented in the letter he wrote to Professor A. Vallisneri the younger on March 30, 1759. Arduino proposed a classification of Earth's rock into four great "orders": primary, secondary, tertiary, and quaternary. This work was a first attempt to apply systematic subdivisions to rock sequences. The subdivisions he proposed formed the foundation of the modern geologic column. Arduino's system was used extensively to describe rock sequences throughout Europe, and even the first geologic map of North America is based on his system. Hutton's 1785 paper, "Theory of the Earth, or an Investigation of the Laws Observable in the Composition, Dissolution and Restoration of Land Upon the Globe," was one of the first to state that the Earth's geologic features were the result of ongoing processes and events. As Steno's principles of superposition and original horizontality, Arduino's classification system, and Hutton's principle of uniformity became more widely disseminated, the stage was set for the project known as the geologic column.

William Smith, a surveyor who worked for canal builders at the end of the 18th century, arguably contributed the concepts and publications that actually shaped the geologic column. He noticed that not only did rock layers themselves seem to correlate across broad distances but also the fossil content of the rocks

correlated. This led Smith to use the concept of "faunal succession" in addition to superposition to correlate the strata and the fossils of England in a map based on a time sequence. Smith, a commoner, found himself fighting an uphill battle to get his ideas published. At one point, he ended up bankrupt and in debtor's prison before a map publisher paid his way out of jail and eventually published his geologic map. This map, published in 1815, was the first iteration of the geologic column as we know it. With this publication, Smith single-handedly created the science of biostratigraphy and provided a means of correlating strata across large distances and across missing sections.

In 1830, Charles Lyell published the first of three volumes, collectively titled, *Principles of Geology*. In this work, Lyell summarized the history of the scientific works of geology to that point, expanded upon Hutton's uniformity, and laid the foundations for future geological studies. His treatise also included detailed investigations of faunal and floral succession through time, the processes of fossilization, and the idea of the same gradual processes observed today being responsible for the features preserved in the geologic record. With these volumes, Lyell formalized the study of geology and created the framework within which the geologic column has been created.

Since then, literally thousands of researchers have contributed, and the geologic column is being constantly fine-tuned. Today, the accepted geologic column is the one certified by the International Commission on Stratigraphy and its parent organization, the International Union of Geological Sciences. Information currently used comes from a variety of sources, including lithostratigraphy, biostratigraphy, magnetostratigraphy, and radiometric dating. Technology continually allows more precise observations, and the column is constantly being remodeled to reflect the more precise information. What started out as a simple observation of time correlation in the Earth's sediments has now grown into an effort to catalogue each rock unit on the Earth and accurately place it within the column. These correlations have, in turn, allowed discoveries of important mineral, oil, and coal deposits and have greatly enhanced our understanding of the processes and events that have shaped our world.

GEOLOGY

Perhaps the most dynamic concept of modern geology is tectonic shift. The theory is based on the fact that the surface of the Earth is not of one piece, nor are the different pieces stable. The Earth's surface is actually composed of a series of 12 massive geologic plates. As Kathy Svitol writes in *Savage Earth*, "The pieces of the shell are Earth's tectonic plates and they float across a layer of soft rock like rafts in a stream, their motions driven by forces generated deep in the Earth. At their boundaries, the plates spread apart, converge, and slide past one another."

These boundaries are the most geologically active regions on Earth. Here, new land is born of the Earth, and old land is consumed. Hot springs spew out mineral-rich waters, volcanoes erupt, and earthquakes tremble, resulting in devastating tsunamis, floods, and mudslides.

When these plates come into collision with each other, one usually slides over or under another, and this is when earthquakes occur. If such an earthquake takes place on the ocean floor, the resulting seismic shock can generate one of the most destructive forces in nature: the tsunami, or tidal wave. On the open seas, a tsunami wave can travel at speeds up to 500 miles per hour, almost as fast as a modern jetliner. On December 26, 2004, a seaquake took place that may have measured as

high as 9.3 on the Richter scale, making it one of the most powerful earthquakes in history.

The seaquake originated off the island of Sumatra in Indonesia. Soon, it led to one of the worst natural disasters in modern history. Tsunamis spawned by the quake became waves of destruction that were carried as far as 5,000 miles from the epicenter, the point of origin of the quake. People were killed as far away as the coast of Africa in Kenya and Somalia. Perhaps the farthest extent of the tsunamis' rage was Port Elizabeth in South Africa, where people were washed away.

By far the hardest-hit countries were Indonesia, Thailand, India, Sri Lanka, Bangladesh, and other nations in South Asia. Estimates of the casualties can never be accurately made, since tens of thousands may have been washed out to sea again after the savage waves receded into the Indian Ocean. Some 300,000 people are thought to have died as a result of the tsunamis, and the count was not yet complete in early 2005. In Indonesia in particular, 500 bodies a day were still being found in February 2005, and the count was expected to continue past June.

A massive international relief effort continued to aid those who survived one of nature's worst calamities. Tragically, the earthquake hit one of the poorest regions of the world as well, where daily life, even before the tsunamis attacked, was a precarious challenge. It is a sad fact that the Indian Ocean tsunamis of December 2004 have probably not yet claimed their last victim.

— John F. Murphy Jr.

GEOMAGNETISM

The magnetic phenomena exhibited by the earth and its atmosphere is known as *geomagnetism*. The strong magnetic field generated from deep within the earth is continually monitored and studied, allowing scientists valuable information for precise indexing of time (geochronology, paleomagnetism), determining crustal position (paleogeography), and abetting perhaps the most important revolution to unify modern geology: plate tectonics.

Magnetism is a force of attraction and repulsion between various substances brought on by the motion

of electric charges of atoms. All planets in our solar system and several corollary moons have some variety of magnetic field that is distinctive to each body.

The Earth's magnetic field is similar to a typical bar magnet acting as a dipole, where the magnetic force is concentrated at the north and south poles. The north magnetic pole is defined by the direction that a north-seeking magnet would tend when used near the planet. These poles are not generally located at the poles of rotation for a planet. At present, the Earth's magnetic poles are approximately 11.5 degrees off the axis of rotation and are continually in motion.

A magnetic pole sets up a field in the space around an object that exerts a force on magnetic materials. The field can be visualized in terms of lines of induction or isolines drawn on an isomagnetic chart. The strength of the main magnetic field is mapped on isomagnetic charts. The contour lines representing constant values for horizontality are called *isolines*. However, the main polar fields are not the only sources of magnetism in a planet. Charts are individually drawn for the other components as well, such as nondipolar elements and for the total intensity. On Earth, there are many nondipole elements composing the total magnetic field that are local and more complicated than the main field. These additional elements make the Earth's total magnetic field more intricate and can be furthermore utilized for a more comprehensive understanding of the Earth's interior. The Earth can be seen to have an amalgamated field consisting of a strong dipolar main field and a superimposed nondipolar field, also known as the *lithospheric field*. Localized lithospheric magnetization, subsurface counterflow fluids processes, and magmatism create the independent multiple nondipolar poles.

From the clues and measurements of the ferromagnetic rocks and direct reading of the earth's magnetic field, scientists are able to glean some information as to how this phenomenon works and how it perpetuates. The field is self-perpetuating, and the present source of the field is called the "Magnetohydrodynamic Dynamo." Paleomagnetized rocks show that the Earth's magnetic field is continuously regenerated and has been doing so for over 3.5 billion years. This is thought to be due to a well-working convection mechanism inside the Earth in which hot fluid rock circulation facilitates electric currents and magnetic fields as Earth rotates. The differential rotational movement of Earth's layers furthermore complicates the motion of the fluid through a resistivity at the boundaries and a torque

exerted by Earth's rotational movement known as the "Coreolis effect." The currents and the induced magnetic flux interact, with the existing magnetic field dissipating or reinforcing it continuously. These processes in concert with the Earth's rotation are predicted by the Magnetohydrodynamic Dynamo theory, which attempts to explain the perpetuation of the earth's magnetic field.

The configuration of the earth's magnetic field as a dipole allows for a phenomenon of colorful curtains that appear to dance across the sky. Known as auroras, they can extend for 100 km arcing near the northern (boreal auroral zone) and southern (austral auroral zone) latitudes. Auroras are the signatures of charged particles that are constantly bombarding the upper atmosphere. As the electrons traveling along a magnetic field line enter the high-altitude atmosphere, the collision with a higher-energy particle strips an electron from the air molecule. This ionizes the molecule and increases its electrical conductivity, releasing a photon of light and giving the auroras their distinctive appearance.

Through the science of geomagnetism, the study of the earth's interior has been greatly advanced. The complexities of the magnetic field beyond the dipolar orientation have allowed for a more complete picture of the interior of the earth. However, it is the dipolar element to the field that humanity relies on most for beauty and protection. The same field that generates the striking auroras in the northern and southern latitudes also protects the earth from the sun's harmful radiation. Without such a field, the earth could have never developed and flourished, teaming with life and wonderful splendor. Humans, as indeed all life, owe our very existence to the dynamic processes deep within the earth that we are just starting to recognize and understand.

Geomythology is the branch of geology that aims to discover the relationship between various ancient people's myths and the geological environments where their early civilizations developed.

The long history of the human being, *Homo sapiens*, is divided into two long periods: the historic period that starts with the invention of writing and the prehistoric one. For the purposes of geomythology, the prehistoric period should be further divided into two subperiods, specifically, when *Homo sapiens* is in the hunting-and-gathering stage (a food gatherer) and a later one, when *Homo sapiens* is a food producer, that is, after the initiation of agriculture and mainly after the cultivation of wheat.

The mythological period is the prehistoric period that refers to the acts of gods, deities, and heroes. These acts may not have been recorded in writing but have remained in the memory of different people, either through tradition or as they were later recorded by various authors. These texts constitute the different mythologies. Such characteristic texts are the "Gilgamesh epic," which refers to the people of the prehistoric Mesopotamia, and Hesiod's "Theogony," which represents the mythology of the Ancient Greeks.

Most people believe that the modern geoenvironment of a place, particularly of a coastal area, remains almost invariable, meaning that whatever landscape contemporary people see around them, no matter on which place on Earth they live nowadays, is the same as that seen by their prehistoric predecessors. This point of view is inaccurate, because the geoenvironment does not remain the same, but constantly changes. In fact, the geoenvironment that we can see around us was created in approximately 5,000 to 6,000 years BP (before the present). This period is known as "Holocene Climatic Optimum." Before that period, everything was different, especially in higher latitudes where the paleogeographic conditions were totally different in land areas as well as in coastal areas. On the contrary, in lower latitudes, the paleogeographic changes were very important, mainly in coastal areas, while at continental and intracontinental areas, the changes are of lesser importance, even though they still exist.

Examples from different parts of the Earth exist where these geographical-relief morphology changes

are so drastic that the present-day picture is totally different compared to prehistory. For example:

1. The Persian Gulf did not exist until 12,000 BP.
2. The Sahara area became a desert just after the 5th millennium. Before this period, the climate in Sahara was more favorable for the prehistoric inhabitants of the area, as a great number of hydrotopes and even lakes existed between 4,500 and 8,500 BP.

Prehistoric people created gods directly connected to their geoenvironment. In the Scandinavian mythology, for example, ice is often related to the myth, while ice is nonexistent in the synchronous mythologies of the people of tropical Africa. Some gods, however, were common in almost all ancient mythologies. For example, the sun and the moon have been deified by nearly all prehistoric people. In most ancient religions, the sun belongs to the early generations of gods; in Greek mythology, the sun belongs to the fourth generation of gods but not to an older one.

The main physical and geological factors related to the ancient mythologies are some geodynamic phenomena, especially volcanoes and earthquakes. Another factor is the climate, mainly the climatic fluctuation during the last 18,000 years. The impacts of the climatic changes are various, but the ones that played a major role in the cultural development of *Homo sapiens* are

The variation of the extent of land covered by glaciers

The sea level changes

The shoreline displacements

All three consequences are connected to the fact that water, under the climatic conditions of our planet, is presented in three different forms:

as gas (clouds, vapor, $H_2O[g]$)

as solid (ice, snow, $H_2O[s]$)

as liquid (saline water, fresh water, surface or groundwater, $H_2O[l]$)

The total quantities of the chemical compound H_2O that are bound in each phase are directly connected to the mean global air temperature of the Earth atmosphere during a particular time period.

On the other hand, it is accepted that the total quantities of water on our planet are stable, at least during the Cenozoic era (last 65 m.a.). This means that under different climatic conditions, while the quantities of the partial phases may vary, the sum of these three phases remains constant:

$$\text{H}_2\text{O(s)} + \text{H}_2\text{O(g)} + \text{H}_2\text{O(l)} = \text{constant, whereas}$$

$$\text{H}_2\text{O(s)} / \text{H}_2\text{O(g)} / \text{H}_2\text{O(l)} = \text{variable}$$

But we know that the climate changes periodically, connected primarily to astronomical causes. According to the Milankovitch theory, the Earth's climate depends on the solar radiation received by the planet, which in turn depends on the Earth's orbiting movement around itself and around the sun. So, finally, the quantity of solar radiation reaching the Earth depends on the *precession* of the Earth axis, the *obliquity* (the change in axial tilt), and the *eccentricity*. Because these parameters are not constant but present a periodicity, the climate changes also present a similar periodicity, which is the combined result of the partial ones.

These geoenvironmental changes were so important that they have forged the religious conscience of the prehistoric people during the most critical time of their evolution, which is the period of the transition from the food-gathering stage to food production stage.

The relationship between the myths of a people and its geoenvironment is in some cases direct and in others indirect.

Direct Relationship Between Gods and Geoenvironmental Factors

The relationship is direct when a god, a semi-god, or a hero is identified with a geological phenomenon. A characteristic example of such a case is God Hephaestus of the Greek mythology or Vulcan of the Roman mythology, who are the gods of volcanoes and volcanic activity in general. In this particular case, the relevant geological phenomena concerning the upsurge of magma toward the surface of the Earth have also been named after these gods.

The responsible deity for earthquakes in Greek mythology was initially a giant, Enceladus, who later was replaced by Poseidon, who was at the same time the god of water. This replacement took place after

the Gigantomachy, when the generation of giants was defeated by the generation of Zeus.

Indirect Relationship Between Gods and the Geoenvironment

Tales of various mythologies do not correspond to reality but are inventions of the minds of the human beings who lived during this distant era. These views are probably connected to the fact that we have not yet realized the great changes that took place in the geoenvironment between 18,000 BP and 6,000 BP, especially at regions bordering the sea and along coastlines in higher latitudes.

During the Late Palaeolithic, the Mesolithic, and almost the whole Neolithic Eras, the coast geomorphology of the entire planet changed so much that it is impossible now to recognize the original coastal geomorphology. The most striking examples are the Aegean Sea (Hellas), the Persian Gulf, the region of Australia, and the coasts of Polynesia.

In the Aegean Sea 18,000 years ago, for example, both the number and the shape of the islands were entirely different, while the present Persian Gulf did not even exist, as the Indian Ocean extended up to the Straits of Hourmouz. These occurred because the sea level dropped at least 125 m during the glacial period, mainly due to climatic-eustatic movements. After a gradual rise in temperature and the commencement of glacier melting, water flowed from the glaciers into the oceans and caused the gradual rise of the sea. Coastal areas were inundated. This physical-geological regime, which commenced around 18,000 BP, continued until 6,000 BP. This means that the inhabitants of the planet's coastal areas watched the land on which they lived being engulfed by the sea, either rapidly or slowly but continuously for 12,000 years. During the same time period, earthquakes, volcanic activity, tsunamis, and other natural phenomena caused disasters from time to time.

We also have to take into account that, during the same period of time, *Homo sapiens* performed a great cultural, economic, and social revolution by inventing agriculture. The climatic change of 18,000 BP commenced when *Homo sapiens* was a food gatherer and hunter and ceased when man became not only a farmer but also developed navigation, trade, ceramics, and metallurgy.

To be able to realize the social-psychological reaction of the people of the era under flooding, we must

imagine how our society would react if the residents of Manhattan, Shanghai, Bangkok, or Piraeus ascertained that the sea level had begun to rise slowly and steadily for many years, for thousands of years, accompanied by all the consequences. Moreover in some other cases, as for example in Greece, in Indonesia, and in Japan, in addition to this sea level rise, volcanoes, earthquakes, tsunamis happened from time to time. This is how dwellers near the sea formulated many of their myths during this era. For the inhabitants of the regions of higher latitudes, such as Northern Europe and the Northern America, or people who lived on high altitude areas, such as the Alps, the retreat of the glaciers was accompanied by the migration of the inhabitants from the south to the north, in the first case, and from lower to higher altitude areas, in the second. This was the physical-geological scenery when the humans of this prehistoric era gradually formulated many of their myths, depending on the geographical environment they lived in and its local physical-geological peculiarities.

Geomythology tries to discover the connection that is hidden behind each myth with the paleoenvironment of a period. Because some of the earliest and most important human civilizations have been developed in areas around the East Mediterranean Sea and the Persian Gulf, we shall use these areas as striking examples of events described in the mythologies of these people.

The Destruction of Eridu

The Sumerians were the first ones to settle Mesopotamia in the middle of the 5th millennium BC. Sumerians invented cuneiform script and believed in life after death. Two of the most important gods to the Sumerians were Enki, who was the god of water, and Enlil, who was the god of wind.

The oldest city of Mesopotamia was Eridu, which is located at the southeastern part of the area, out of the Euphrates River. Some other well-known cities of this time are Ur and Uruk. Every city had its own protector god. The protector god of Eridu was Enki.

The myth says that Inanna, the goddess of love, was concerned about a new town, named Uruk, although it had neither the power nor the prestige of other new towns. During a symposium of the gods, Inanna seduced the god Enki, a philanderer who was drunk. At some moment and in exchange for her love,

Inanna asked Enki to reveal the location of the “one hundred divine powers” that protected Eridu. As soon as Enki revealed the secret to her, Inanna escaped and took the one hundred divine powers from Eridu to Uruk. Enki never managed to save Eridu from decadence since that time, while Uruk gradually became one of the most powerful towns. Enlil, the god of wind, took Enki’s position. Enlil continued to be more powerful than Enki, and thus according to the Sumerians’ mythology, the city of Eridu has been without any trace of human life since, due to the desertification that followed the era of climatic optimum of the Holocene. In the same era, we have observed a similar change of climate toward arid conditions in other areas of the Earth, with a prime example being the Sahara desert.

The study of recent continental sediments, such as lacustrine deposits, paleo-soilsm and aeolian deposits found in the driest parts of the modern Sahara desert, has shown a succession of dry and wet climatic phases. According to Petit-Maire, at the end of Pleistocene, a phase of intense drought took place that reached its peak around 18,000 BP.

It appears that the paleoclimate in Central Europe follows a different course from the Sahara one, the Dead Sea, and Mesopotamia. While in central Europe, the climate was dry, in the Sahara, the Dead Sea, and Mesopotamia, a humid phase began that lasted from about 9,000 BP up to 4,500 BP (2,500 BC). It appears that the most favorable period in the region is temporally extended up to 4,500 years ago. During this wet phase, archaeological settlements have been discovered, dated between 8,200 and 6,800 BP, when the lakes reached their greatest extent. Since then, a dry period begins that extended up to 4,500 BP (2,500 BC). The conditions in the Sahara became unfavorable to the prehistoric inhabitants, the settlements were abandoned, and there are no similar archaeological findings since then.

Humans lived in this region for a relatively small time interval. The first settlements dated to $6,980 \pm 320$ years BP, while the last ones around $5,700 \pm 100$ BP. Consequently, the conditions in the Sahara were favorable, or relatively favorable, for the humans only during this period. As similar climatic conditions should happen in Mesopotamia during the same time period, the replacement of Enki, the god of water, by Enlil, the god of the wind, in Eridu is directly connected to the change of the climatic conditions of Eridu area.

Sodom and Gomorrah

The description of the total destruction of Sodom and Gomorrah is given in the Bible (Genesis 19:25). The precise position of the city of Sodom is not known, but some suggest it may be near Mount Sedom, on the east of the southern basin of the Dead Sea.

The Dead Sea is an active tectonic graben, which is bound by two roughly parallel faults. The faults are part of the central segment of the major north–south trending crustal rift separating the Arabian lithospheric subplate, on the east, from the Sinai, on the west. The Arabian subplate has been moving north continuously since the Miocene. The many faults in the Dead Sea region show continued seismic activity with a maximum earthquake magnitude of 6.9 (Richter scale) in the time period from 1909 to 1993.

Some geological evidences of a left-lateral fault movement and a great subsidence of the sediment filled basin and some others indicate that it was most likely a great earthquake that destroyed Sodom and Gomorrah.

The Struggle Between Greek Mythological Gods

The oldest and greatest poets of ancient Greece—Hesiod and Homer—wrote of the struggle between generations of gods or between gods of the same generation. This struggle sometimes resulted in the extinction or disappearance of whole god generations (for example, Titans or Giants), and some later used the struggles as an excuse to accuse the gods of the ancient Greeks of being immoral, cunning liars and criminals.

The struggles of these ancient gods, however, described in Greek mythology through the works of Hesiod, Homer, and others, reflect the physical and geological evolution of areas of the Aegean during the time between 18,000 and 6,000 BP.

The Greeks considered Heaven and Earth as the first generation and parents of Gaia (Gaea) or Mother Earth, whom they considered the oldest of their deities and the primary creator, born of Chaos itself. According to the myth, Earth brought forth Uranus (the Heavens) to be Gaia's mate, and the couple gave birth to the third generation of gods that included, among others, the Giants and twelve Titans.

The first struggle recounted in Greek mythology takes place when Cronus, a third-generation god and leader of the Titans, tried to overturn his father Uranus's power through assassination. Cronus did not succeed.

Gaia stood by Uranus during this difficult time and through her contribution, the Giants were born.

Gaia and Uranus's son, Cronus, with another Titan, Rhea, parented the first six Olympian gods, among them Poseidon and Zeus. Cronus feared that his sons would eventually take over his power and, as he did with all his sons, he tried to eat Poseidon and Zeus at birth. Their mother Rhea protected them by deceiving Cronus. When Poseidon was born, Rhea told Cronus that she had not given birth to a child but to a small horse. In the case of Zeus, Rhea replaced the infant with a large stone, which she gave to Cronus to eat.

Subsequently, the children of Cronus and Rhea, which now made up the fourth generation of gods referred to as the Olympians, competed initially against the Titans in a battle known as *Titanomachy* (Titanomachia). The third-generation Giants assisted the Olympians in their battle against the Titans. Then the tables turned, and, in a second battle known as the *Gigantomachy* or *Gigantomachia*, the Giants fought the Olympians.

Through these battles, the Olympians exterminated the Titans and Giants and began their own period of dominance. Their reign was not without difficulties: the struggle of Zeus and Poseidon, Poseidon and Apollo (Delphi and Corinthos), Poseidon and Athena (for the protection of the city of Athens), Demeter and Hades, and others. In most of the battles, Gaia played a primary role, and the elder brother, Poseidon, was gradually defeated by his younger brother, Zeus, as well as by Apollo and Athena, who are gods of a younger generation. By these struggles, the older generations of gods have been replaced by younger ones.

From a geological perspective, the struggles of the generations of gods should have occurred during the time period of about 18,000 and 4,000 years BP. This time coincides with changes of the physical and geological regime in the Saronic Gulf, the Aegean, and circum-Aegean areas.

The physical-geological evolution of this period follows.

The last interglacial period begins at approximately 18,000 BP and spans to our times.

18,000 years ago, the sea level was around 125 m lower than the present shoreline. Between 18,000 BP and 6,000 BP, the sea level rose from 125 m to 2 m. Scientists have estimated that the rising rates varied from 1 cm/y–5 cm/y.

The rising of the sea resulted in a relative subsidence of the coastal areas, that is, a transgression of the land and permanent flooding of several coastal areas.

The rate of this transgression was different from place to place, depending on the slope of the landscape and varied from some meters a year rise to many hundreds of meters a year.

The result was a new physical-geological regime—permanent flooding conditions of several coastal areas—that replaced the older regime when the global air temperature remained more or less stable for many thousands of years. Evidently, the inhabitants of these areas suffered, and the catastrophes were enormous. In addition to the flooding conditions, earthquakes, tsunamis, and volcanic activity were continuously present, as Greece, from a geotectonic point of view, is a seismically and tectonically active arc.

The upper Paleolithic and Neolithic *Homo sapiens*, who were living in areas under the flooding regime, believed that very strong gods were responsible for all these disasters and general catastrophic phenomena, some primitive, some evil, gods who were active throughout the period of the climatic changes. During the same period, the upper Paleolithic inhabitants of the Aegean area needed to pray to benevolent gods to save them from the disasters caused by the primitive gods, so they created the fourth-generation gods Poseidon, Zeus, and so on. After the climatic stabilization (around 6,000 years BP), the evil gods were defeated by the benevolent gods. Thereafter, the struggle among the Olympians concerns a rearrangement of jurisdictions. As the new climatic regime required more water and a god who could regulate precipitation was more important than Poseidon, Zeus replaced him.

Hercules and the Lernean Hydra

In ancient Greek mythology, Hercules is one of the most famous heroes, known primarily for his labors, most having to do with fresh water and land reclamation. Water came either from karstic springs, such as that in the Labor of Lernean Hydra near Argos (Peloponnesus), or from lakes, such as in the Labor of Extinguishing the Birds in Stymphalia Lake (Central Peloponnesus), or from rivers, such as in the Labor of Cleaning the Stables of Augias, near

Olympia. Apart from these labors, there are more, but not so well-known, such as those that relate to other rivers, thermal springs, or the destruction of draining sites.

The myth of extinguishing the Lernean Hydra is one characteristic example of a myth coinciding with the hydrogeological conditions of the area. The essence of this myth follows.

A repulsive snake-formed beast (the Lernean Hydra) lived in Argos, a region near Lorna Lake in eastern Greece. It had an enormous serpentine body ending in several snaky tresses with a head at each edge. The beast's breath was poisonous, and often it would spit out fire, even while asleep, which would destroy everything in the plain, including crops, animals, and even people.

Descriptions of the number of the Hydra's heads varied.

- On a reddish jug of 480–470 BC and on other representations as well, Hydra is shown with 12 heads.
- According to the ancient authors Alkaios and Apollodoros, Hydra had 9 heads.
- On clasps of the geometric period, Hydra is depicted with 5 or 6 heads.
- According to another author, Symonides, Hydra had 50 heads.
- According to Euripides, Hydra had 100 heads.

However many heads were presented, all agreed that Hydra's central head was immortal. In addition, the myth informs us that Hercules faced Hydra with a sword, a cudgel, or stones, and that when one head of Hydra was cut, two new heads sprouted.

The spring Lerna is a typical karstic spring, hydraulically connected to some sinkholes located at the bottom of a mountainous karstic basin. The connection between the myth and the geoenvironmental conditions is not obvious, but when we know the hydrogeological condition of the area, the geomythological interpretation is relatively easy.

Some of the hydrogeological characteristics of Lerna include

- The discharge of the spring's system occurred at several points.
- The altitude is at 0.50–1m, above the present sea level.
- In 1965, the mean annual yield of the main Lerna spring was about 60 by 106 m³/year.

- While the annual discharge is relatively lower compared to some other karstic springs located close to it, the central spring has never been known to be dry.

The number of points where the karstic aquifer is being discharged differs during the year, as we might expect, depending on the season, the mean annual height of the atmospheric precipitation at the regional area, and the duration of the climatic period, that is, if the wet period is a 100-, 500-, or even 2,000-year cycle. In this way, we may interpret the differences in the numbers of the Hydra's heads, because each head can represent a point of discharge of the karstic aquifer and this number differs according to the climatic conditions existing during a longer or a shorter period.

The myth recounts Hercules's attempts to exterminate the Lernean Hydra by cutting off the beast's heads, one by one. This may symbolically represent a spring's discharge at a karstic point that may become possible by placing a rock at the point where the water discharges to prevent its exit or to force it to follow another route.

Geologists know well that the karstified rock body, through which the underground water circulates on its way to the spring, represents a complex system of underground intercommunicating erosion pipes or ducts. In addition, the tectonic discontinuities, even if the karstification is not very intense, are also permeable. Consequently, if we place a rock in front of the mouth of a karstic spring, the water will come out from two other or more side points. This corresponds with the Hydra's heads: each that Hercules cut off became two new heads.

Hercules should have used the sword to cut the thick vegetation that usually exists in the swamp in front of a spring. It is easy to imagine that the vegetation of this hydrobiotope of prehistoric Lerna would have been quite rich and, without fail, richer than that of the present period, especially during the period of the climatic optimum, when the sea level was a little higher than today. Hercules probably used the cudgel to smash the limestones at the spring mouth, and Iolaus, Hercules's nephew and assistant, used the sickle to cut the vegetation and facilitate Hercules's way to the spring, that is, the heads or the central head, as well as to facilitate the flow of water to the sea to dry up the swamp or lake.

GERONTOLOGY

Coined in 1906 by Russian biologist Eli Metchnikoff, the word *gerontology* is historically derived from the Greek word *geront*, meaning “old man,” and *logia*, meaning “the study of.” By definition, gerontology is the scientific study of the biological, psychological, historical, sociological, and economic aspects of human aging. Research is aimed at discovering the processes inherent in aging, as well as the most effective ways in which to apply the knowledge for the benefit of society.

Contributions to the study of the aging process are made from many of the basic science fields. For example, biochemical, genetic, and immunological research provide valuable information on the biological aspects of aging. Cardiological and neurological studies provide gerontologists with insights into the causes, epidemiology, and consequences of disease processes affecting the elderly. Social science and behavioral research are useful in providing gerontologists with a holistic view of the process of aging. Because of this, gerontology can be considered a true multidisciplinary and interdisciplinary field.

as it relies on the contributions of several scientific disciplines.

Disciplines of Gerontology

Historically, concern and interest in the aged of society has existed for thousands of years. However, gerontology as a unique and empirically based field of science is a relatively new concept. Methodological scientific inquiry began as early as the late 16th and early 17th centuries, when Sir Francis Bacon studied the relationship between poor hygiene and rapid aging. Later, Ben Franklin contributed to the legitimacy of the study of aging in his research on the uses of lightning and energy to rejuvenate and to retard death.

By the early to mid-20th century, several basic themes had emerged in the study of aging. One was that the problems associated with aging are complex and can be better understood within an interdisciplinary framework. Second, scientists had begun to recognize that there were social consequences of an aging population, and due to this, there was a need for basic information on both normal and abnormal aging processes. Third, there appeared to be an interaction between one's biological predisposition and the environment that affects age.

Biological Gerontology

This aspect of gerontology focuses on physical longevity and causes of death. Research is directed at

understanding both normal and abnormal physical changes that can be directly associated with an aging biological system. Factors include age-related hormonal changes, cell mutation, wear on tissue, degenerative influences of physical illness and disease, and related functional incapacitation.

Of important interest to the gerontologist is the ability to understand and differentiate between normal aging and pathological disease processes. Age-related changes of the biological system do occur naturally in the normal

population in the absence of illness or trauma. However, it would seem that as we age, we become more vulnerable to disease for a variety of reasons, such as central nervous system (CNS) cell loss, inefficient myocardial functioning, and reduced immunologic response.

Multidisciplinary gerontological research is frequently centered on preventative interventions aimed at extending and improving the quality and span of life. Not surprisingly, findings suggest that exercise and nutrition improve cardiovascular health, increase bone and muscle structure, and reduce weight. Complex genetic manipulation studies have also shown effectiveness toward maintaining and restoring aging biological systems of the human body.

Psychological Gerontology

Psychological concepts such as depression, anxiety, low self-esteem, thrill-seeking behaviors, antisocial personality, and introversion are all variables that can affect the aging process by putting people at high risk for injury or disease. This subspecialty of gerontology looks at the role of interpersonal relationships (social support) and intrapersonal factors (age, gender, cognition, coping mechanisms, and genetics) and their impact on life and aging.

There appear to be several age-related changes that affect cognitive status, in particular, memory functions, the ability to learn new things, intellectual flexibility, and thought-processing speed, all of which can

directly affect one's level of functioning in society. In addition, the elderly deal with a plethora of psychological factors associated with age that younger adults don't typically face (grief, loss of employment status, infirmity) that can complicate or reduce one's ability to deal with stress and change.

Sociological Gerontology

This approach examines how the unique norms and values a society holds can impact individual perception and reaction to growing old. Gerontologists hold that aging itself is a socially defined and constructed process. The ways in which a society conceives of the capabilities and expected roles of its older members vary by location, historical time period, religion, and culture. For example, the role a 75-year-old woman plays in an extended family might be much more involved in an Asian society compared with an industrialized Western society.

In addition, there appear to be political and economic factors that can influence the process and quality of human aging and life expectancy. These factors include national industrialization, sanitation, diet, hygiene, poverty, harmful substance exposure, medical accessibility, and infant mortality rate.

Gerontology vs. Geriatrics

Gerontology is often confused with its sister science, *geriatrics*, as both are concerned with the biological aspects of aging. However, geriatrics is more restricted in scope, concerning itself primarily with clinical diagnosis and medical management of disease and illness within the elderly population. Geriatrics is the study of the medical aspects of old age and suggests an active role as practitioner, or caregiver. In contrast, gerontology strongly implies a scientific mission, focused on the understanding of the etiology, frequency distributions, and consequences of disease and illness.

Technological and medical advances in the late 20th and early 21st centuries have contributed to the increase in size of the aged population. As the scientific community continues to search for more effective treatment methods and cures for disease and illness, it is likely that this population will continue to grow. As such, it can be assumed that interest in the field of gerontology will rise at a similar rate in an effort to meet the social, economical, and psychological needs

of the elderly. Future research in gerontology will likely be applied to the development of new and improved treatment and social policies intended to improve the quality of life and extend the years of healthy functioning among the rapidly increasing aged population.

Gesellschaft, which I will here translate as “society,” is one of the most ambiguous sociological notions. One talks about caste societies, class societies, open and closed societies, agrarian, socialist, capitalist, industrial, civil, and pluralist societies, static and dynamic societies, and many other types of societies. All types of societies are particularly being dealt with within *sociology*, a term coined by A. Comte, which can be translated as “study of societies.” Society in the German context is mostly contrasted with the term “community” (*Gemeinschaft*).

Historical Background

In Ancient Greece, the terms associated most directly to society are *κοινωνία* (community/society), *πόλις* (city/state), *οἶκος* (family/household), and *φιλία* (friendship). All four terms are of central significance in the ethical theories of Plato and Aristotle. According to Aristotle, the terms *κοινωνία*, *πολιτική*, and *πόλις* are synonymous. There are societies based on nature (husband/wife, parents/children, master/slave) and

others based on agreement (some laws of a city-state). According to Aristotle, human beings are political animals, which implies that human beings can only be *eudaimonious* (live a good life) within a city-state, a civil society. It can be discussed whether a πόλις is a type of society or community. The political leaders have to be free male citizens who rule above other free male citizens who are their equals; unfree slaves; children who are not yet free human beings; and free women who are slightly subordinate to free male citizens. It is clear, however, that for Aristotle, human beings were divided up into the free and the unfree, without there being the concept of equality of all human beings, which is closely linked to the concepts of human rights and human dignity.

In Roman antiquity, the notion *κοινωνία πολιτική* was translated as *communitas*, *conciliatio*, *societas civilis*, *societas humana*, and *societas* by Cicero. Cicero was the first to hold that all human beings are equal because of their dignity as human beings, and he did refer to all human beings as belonging to the *societas humana*, or to the *societas*, and when referring to all human beings, he normally employed the term *societas*. It needs to be stressed that it can be problematic to employ the term *society* in order to refer to humanity as a whole, because in that case, a sociological notion and a term for a species is being mixed up, as L. Gumpłowicz has already pointed out. When referring to human organizations that have more in common (family, friendship, city-state), Cicero, on the other hand, tended to use *communitas* more often. It would be misleading, however, to hold that Cicero already had a clear-cut distinction between societies and communities. It can only be said that he employed the term *societas* to refer to all type of human organizations, the largest being the group consisting of all human beings and the smallest being related to family and friends.

From the 13th century onward, the Aristotelian *κοινωνία πολιτική* was translated as *communitas*, *communication civilis*, or *politica*. In the same century, Thomas Aquinas introduced the distinction between a public and a private society, which can be related to Aristotle's πόλις/οἶκος distinction. During the Enlightenment, Hobbes identified the civil society with the Greek πόλις. A similar position was presented by Locke in the *Second Treatise of Government*, in which he wrote a chapter titled "Of Political or Civil Society." In the same century, English moral philosophers (A. A. C. Shaftesbury, A. Smith) employed the

term *society* to refer to civil societies. Around 1800, German writers (Herder, Goethe, Schiller) used the term to refer to civilized humanity in general. Kant identified the state (*civitas*) with the *societas civilis*, and Hegel, in his philosophy of law, understood the state (synthesis) as the combination of family (thesis) and civil society (antithesis). A basic thought in Marxist theory is also concerned with societies. It is claimed that the history of all past societies is the history of class struggles.

Ferdinand Tönnies

Tönnies's work *Gemeinschaft und Gesellschaft* (Community and Society) contains the most influential discussion of these terms for German sociological theory. Here, his description of a society is summarized as follows:

In a society, individuals with arbitrary goals are brought together, which is the reason why societies have to be governed by obligatory rights. Societies demand people who live in big cities, stick to conventions and public opinion, and live a cosmopolitan life.

Given this background, it becomes clear what Tönnies means when he claims that a society is something public, is linked to the world, to trade, to the sciences. A joint stock company is a type of society but never a community. A society is always something transitory and artificial, as it is rather like a machine that is there for some purpose, as opposed to a living organism. Human beings within a society also live together peacefully but without being much connected to one another, separated from another like disintegrated atoms. No deeds come about due to an existent solidarity, unity, a feeling for the others, but rather each one does what is good for himself and lives in a permanent tension with the others. No one does anything for anyone else without expecting anything of at least equal value in return. The laws of exchange are important, and the subjective exchange values become the absolute criteria for value. These individuals can be serving a society by serving themselves, and they are dependent on a society. Money in such a system is a way of regulating the exchange and becomes particularly important. Each good is equivalent to an amount of money, and the better a good is, the more money one gets for it. The system is based on scientific reasoning. When two people exchange goods, it is done on the basis of a contract, which is a place where two singular wills or individuals can

meet. Contracts are often made without explicitly formulating them. All things including one's work turn into a good. This is the reason why civilized society is an exchange society. However, it is natural to create order to enhance the preservation and promotion of pleasure in a community, but the trade undertaken in a society is the opposite of such behavior. One does it to enhance and support only one's own interests. Tradesmen and capitalists (the owners of money) are the lords and leaders of a society. People without money do not have any rights; they are like slaves. The tradesperson is educated, without a home, is knowledgeable of foreign morals and arts, without love and piety for a particular culture, speaks many languages, is well spoken, is adaptable, changes and adapts his character according to his surroundings, and employs everything to his own advantage. Tradespeople buy things not because they are in need of them, but in order to sell them for more money. The difference is the gain. Three deeds describe the structure of a society, namely, to buy work, to employ work, and to sell work as products and pay much less for the work and the raw material than you receive for the final product. The meaning of making money is to exchange the money into semiluxury. Money is power, but it has to be given away in order to receive something for it.

Current Western states are closer to societies than they are to communities. Capitalism is dominant in them, the importance of traditional families diminishes, people think globally, they travel, live in foreign countries, and thereby lose and abandon their traditional organic roots. All these are reasons that make it necessary to classify our Western states as societies. Whether this is praiseworthy or not is a matter of dispute. A contemporary discussion in the English-speaking world in which Tönnies's distinction could have been employed was the liberalism/communitarianism debate. Liberalism can be linked with Tönnies's understanding of a society, and communitarianism with his understanding of community.

Tönnies's distinction is also closely associated with the culture/civilization distinction in the German-speaking context, whereby the society/community distinction includes only types of human organization, whereas the culture/civilization distinction not only refers to types of human organization but also includes the ideas and works created by the respective human beings. All cultures include a community, and all civilizations a society. In the Middle

Ages, in Europe, Christian culture was dominant, and human beings were all part of a community with close, organic ties. At the end of the 20th century, European states represented models of pluralist civilizations in which the importance of the individual is extremely strong and human beings are part of a society.

Karl Popper

Karl Popper introduced another currently significant distinction, namely, that between an open and a closed society. Both represent types of social order. In contrast to a closed society, an open society sets free the critical ability of human beings. The different notions can be distinguished on a sociological, historical, and ethical level. Concerning the sociological aspect, the notion can be employed to describe contemporary social organizations. In that respect, they can be compared to Tönnies's community and society. Concerning the historical aspect, Popper regards the two types of society as separate developmental stages in cultural history, whereby the closed society came first, and it was replaced by the open society only during the last couple of centuries. According to Popper, this transition was one of the most important revolutions in the history of mankind. Closed societies were held together by eternal laws, morals, and taboos. The herd or the tribe formed a semiorganic unity, with the members being connected in a semibiological way. All decisions had to be approved by the tribe, and thinking was collective. Open societies, on the other hand, are constituted of individuals who have to make personal decisions and have to employ their own critical abilities in order to grasp situations and give structure to their lives. The third aspect on which Popper's distinction can be analyzed is the ethical. He polemicizes against Plato and Hegel by accusing them of totalitarianism, upholding an ideal of rationality, which according to him can be the only basis for a humanitarian attitude.

Final Thoughts

It seems as if Popper's distinction between open and closed societies bears many similarities to Tönnies's between community and society. Given the vast variety of contemporary positions concerning social organizations, it might be useful to employ Tönnies's basic distinction and then distinguish between an

open and a closed version. In that case, we would have an open and a closed community, and an open and a closed society. An open society would be one in which a worldview like R. Nozick's libertarianism is predominant. A closed society is still based on liberalism and pluralism but has a greater amount of formal aspects in common, as in G. Vattimo's philosophy, which stresses the aesthetic elements of Catholicism. In a closed community, one specific worldview would be dominant, as is demanded by A. MacIntyre, who upholds that a return to a pre-Enlightenment type of Christianity would be desirable. An open community, on the other hand, does not try to determine the behavior of human beings in all aspects, but intends to promote some important basic virtues within a liberal environment, as is the case in H. Küng's Weltethos theory. The distinction between open and closed societies and communities was introduced by S. L. Sorgner.

GHOST DANCE

The Ghost Dance originated among the Great Basin Paiute as a religious movement arising out of the extreme social, political, economic, demographic, cultural, and personal stress brought about by the rapid incursion of Europeans and, later, Americans into North America. Anthropologists refer to such movements as revitalization, nativistic, new religious, and/or transformative social movements. As such, they renew past cultural beliefs and practices with

revitalizations of selected aspects of these beliefs, while actively adapting them to various non-Native (usually Christian) beliefs and practices. These movements are also not simply religious but also political and social in their scope.

The 1870 Ghost Dance movement was led by the Paiute prophet Wodziwob, who predicted that the performance of a prescribed dance would bring about the disappearance of all Whites, the return of all deceased Natives, and a restoration of a halcyon pre-contact life. This religious movement primarily spread west to California and Oregon. The Ghost Dance of 1890 was a more widespread spiritual movement that originated under the inspired leadership of the Numu (Northern Paiute) Indian Wovoka (Jack Wilson). The dance was taken up by a large number of Native American groups from the West Coast to the Great Plains. (Other Native American religious leaders who lead movements of this type include Handsome Lake, Neolin, Smohalla, and John Slocum.) While the movement begun by Wovoka is best known in English as the Ghost Dance, the Northern Paiute referred to it as the *nanigukwa* (Circle Dance). Forms of both Ghost Dances continued in California and the western United States and Canada until the 1960s in some regions. There was a brief revival of the dance among groups of Lakota in the 1970s.

The leader of the more influential 1890 movement, Wovoka ("woodcutter" in English) was born between 1856 and 1863. Reputed to have spiritual powers, his father, Numu-tibo'o (Buckskin), born around 1835, and himself took part in the 1870 Ghost Dance movement. Wovoka's mother Tiya was known as a very hard worker whose work ethic became central to Wovoka's religious message. At 14, Wovoka went to the staunch Presbyterian home of the Wilson family, from whom he derived his own English name and elements of his religious teachings. Wovoka married an Indian named Tumma, whose English name was Mary. They had six sons, all of whom died young, and four daughters, one of whom was not fathered by Wovoka. Mary Wilson died in 1932, the same year as Wovoka.

Wovoka previously experienced some minor visions, and it was on New Year's Day of 1889 that he received his Great Vision, reportedly brought on by a severe fever or the shock of a great sound. Wovoka went into a deep trance, "died" along with the sun during an eclipse that day, and returned to life, as did

the sun. While dead, he went to heaven, where he conversed with God and saw many dead people who lived rejuvenated and happy lives. During this trance, he was taught the round dance and instructed to conduct it for 3 to 5 consecutive days at a time. He received five songs that gave him power over the weather. Wovoka also claimed he was invulnerable to bullets and reportedly made ice appear on a hot July 4th. Wovoka validated his spiritual power through trances, his control of the weather, and other extraordinary feats. He stressed that his religion was meant for all people and that it was a religion of peace and harmonious coexistence.

Wovoka instructed his own people in this faith and received representatives of over 30 different tribal groups, including the Pawnee, Shoshone, Bannock, Arapaho, and Gros Ventres. He also communicated with these groups by letter. While different groups adapted his teaching according to their own cultural patterns, the prophet instructed all visitors in the round dance, told them to work hard, not to steal or lie, and to be at peace with all.

Despite Wovoka's message of peace, the Ghost Dance is best known in history as being one of the precipitating factors in the Wounded Knee Massacre. The reconstituted 7th Cavalry was called out during the Ghost Dance on Pine Ridge Reservation and rounded up Big Foot's band, which was traveling from the Cheyenne River Reservation to Pine Ridge on December 29, 1890. Shooting broke out at Wounded Knee Creek while the Lakota were being disarmed, and a general massacre ensued. Between 270 and 300 women, children, and men were killed.

In response to the massacre, Wovoka told people not to dance any more, lest there be more violence. He remained committed to his vision and continued to act as a religious leader and healer, distributing the paints, bird feathers, and Stetson hats that were central to his spiritual practice.

Modern descriptions of the Ghost Dance movements of 1870 and 1890 rely on critical reading of contemporary newspaper accounts of the dance, as well as on missionary correspondence and journals, transcribed Native accounts, documents by Indian agents on the various reservations, and military reports. (With the exception of James Mooney, no anthropologist directly observed these ceremonies or interviewed Wovoka or other participants.) Beyond describing the dance and relating a sequence of historical events, anthropologists attempt to understand

the dance from the Native and non-Native perspectives, and they employ ethnohistoric and symbolic analysis in discussions of the causes of the dance movement. Finally, anthropologists restudy the descriptions and theories generated by their own predecessors to correct the historical record and better understand the social processes and symbolic meanings involved in the Ghost Dance.

In considering any interpretation of the dances, keep in mind that culture is engaged in by individuals, not just groups. Not all Indians would have participated in a local Ghost Dance. Groups and the individuals within them varied in their understanding of the dance. Some groups, such as the Navajo, did not engage in the dance at all because the dead were considered malevolent and not to be summoned back for contact with the living. Wovoka himself felt that some people misinterpreted his teachings.

James Mooney of the Bureau of American Ethnology wrote one of the earliest and most comprehensive accounts of the Ghost Dance. He personally visited Wovoka in 1892, participated in one of the dances, and interviewed many people who had taken part

in this movement. Michael Hittman is the main biographer of Wovoka and chronicler of the Ghost Dance religion. Shelley Osterreich created a helpful annotated bibliography on the Ghost Dance. Alice Kehoe provides broad historical and cultural contexts for this religious phenomenon, and Raymond DeMallie provides an example of an analysis of the Ghost Dance in the specific context of Lakota culture.

GIBBONS

Gibbons are members of the order Primates, family Hylobatidae, and genus *Hylobates*. They are most notably known for their unique vocalizations and long arm spans, which can reach twice the length of their bodies. Slender and agile, gibbons usually locomote using their long arms in a movement known as *brachiation*. Their hands, equipped with long, curved, and slender digits, are used as hooks as they swing from tree branch to tree branch. Some of the smaller species appear to throw themselves from tree to tree, crossing gaps of 10 meters or more. While feeding, however, gibbons often use quadrumanous climbing.

Gibbons are considered to be a “lesser ape.” Like all apes, they are characterized by an absence of tails, broad chests, and an upright body posture. However, unlike the great apes (chimpanzees, bonobos, gorillas, and orangutans), they have smaller cranial capacities and body sizes. In addition, they

are more numerically successful and specifically diverse than the great apes.

Currently, there are 11 species of gibbons, all found in Southeast Asia. The 11 species are generally divided into four subgenera, which are grouped together based on chromosomal numbers and coloration.

The first of the four subgenera has the same name as the genus, *Hylobates*, and is also known as the “lar group.” Lar gibbons have 44 chromosomes and variable pelage colors. Species in this group include the white-handed gibbons (*Hylobates lar*), silvery Javan gibbons (*H. moloch*), agile or dark-handed gibbons (*H. agilis*), Mueller’s Bornean gray gibbons (*H. muelleri*), pileated or capped gibbons (*H. pileatus*), and Kloss’s gibbons (*H. klossii*).

The second group comprises the hoolock or white-browed gibbon (*H. hoolock*), subgenus *Bunopithecus*. White-browed gibbons have 38 chromosomes and are sexually dichromatic. Females are more tan colored than males, which are black. Also, females have whitish hairs encircling their faces, while males have only white eyebrows.

The concolor group, subgenus *Nomascus*, has 52 chromosomes and is sexually dichromatic. Males of the black gibbon (*H. concolor*), golden-cheeked gibbon (*H. gabriellae*), and Chinese white-cheeked gibbon (*H. leucogenys*) tend to be black, while females are buff.

The fourth group is the siamangs, the largest of the gibbons, belonging to the subgenus, *Symphalangus*. Like the *Nomascus* group, siamangs have 52 chromosomes but are not sexually dichromatic. Unlike the gibbons, however, siamangs have webbing between their second and third toes. Also, males are slightly larger than females.

Gibbons mainly live in primary moist forest and spend virtually all of their time in the canopy. The bulk of their diet consists of ripe fruits but may also include leaves, flowers, and small invertebrates. Gibbons live in single, monogamous family units. Monogamy in gibbons is thought to have resulted from the need to spend large amounts of time rearing offspring. With no male to help defend a territory, females may not be able to obtain enough resources to conceive and/or rear the slow developing young. Offspring can stay with their parents for up to 10 years. At this point, they leave the family group and “bud off” (i.e., usurp a part of the parents’ home range) and look for a mate of their own.

Gibbon vocalizations are well-known. Most pairs sing duets in the mornings and evenings, with their

calls carrying for over 1 kilometer. The vocalizations are used for territorial defense, maintenance of the pair bond, and general communication. Gibbon species can be distinguished by their calls.

Due to their propensity to spend their lives in the forest canopy, gibbons are extremely sensitive to habitat loss due to logging and agriculture. In fact, of the 11 species, three are considered to be vulnerable, two endangered, and two critically endangered.

GIGANTOPITHECUS

Gigantopithecus is the name given to an extinct ape discovered by G. H. R. von Koenigswald, in 1935. The two species, *Gigantopithecus blacki* (named after Koenigswald's late friend and colleague Davidson Black) and *G. giganteus* (formerly *bilaspurensis*), are known primarily by teeth and jaws. The first tooth (as

Source: © Russell L. Ciochon.

well as many of the more than 1,000 found after the original discovery) was discovered in a Hong Kong apothecary, where traditional Chinese pharmacists use fossils, referred to as “dragon bones,” in medicinal recipes.

As the name implies, these fossil apes were enormous. Based on the teeth and jaws, *Gigantopithecus* is estimated to have been 9 to 10 feet tall (3 m) and 600 to 1,200 lbs (270–550 kg). They were the largest primates known, more than twice the size of a mountain gorilla.

The great size of *Gigantopithecus* would have required it to spend most, if not all, of its time on the ground. Most scientists believe that *Gigantopithecus* was quadrupedal, walking on four legs. They may have walked on their knuckles, like a modern gorilla, or on their fists, like a modern orangutan. There are also some scientists who believe *Gigantopithecus* was bipedal, walking more like humans. Unfortunately, postcranial elements (such as pelvis or leg bones) have not been found. This makes accurately reconstructing its posture and locomotion difficult.

Because of its massive teeth and jaws, scientists originally believed that the diet of *Gigantopithecus* consisted of hard objects such as nuts and seeds. Later, analyses of residue left on the teeth led scientists to conclude that their diet probably consisted primarily of fibrous leaves. The fact that many of the *Gigantopithecus* fossils are found together with remains of ancient pandas suggests that they inhabited and exploited bamboo forests. Their predominantly leaf diet was most likely

supplemented by fruit, based on the high rate (10%) of dental cavities found in *G. blacki*.

Fossils of *G. giganteus* are known from deposits in the Siwalik Hills of India. They have been dated to the Miocene approximately 6 to 7 million years ago. Fossils of *G. blacki* have been found in China and Vietnam and are much younger. Here, it appears that the species may have lived up to 500,000 years before becoming extinct.

It is possible that the species became extinct when climatic changes caused large die-offs of the bamboo forests they inhabited. It is also possible that competition with giant pandas or early hominins, such as *Homo erectus*, may have caused their extinction.

Since their discovery, *Gigantopithecus* has been interpreted variously as a human ancestor, as an overspecialized side branch of human evolution, or as an unusual fossil ape that had nothing to do with human evolution. Most scientists now recognize *Gigantopithecus* as an extinct ape that was more closely related to orangutans than to African apes or humans.

Some people have suggested that Bigfoot and/or Yeti (abominable snowman) are modern-day descendants of *Gigantopithecus*. However, there is no indisputable physical evidence to support this hypothesis. Scientists generally feel that if these modern-day creatures existed in numbers large enough to be a breeding population, they would leave physical remains and would have an observable effect on the environment.

GLOBALIZATION

The Contested Territory of Globalization

The term *globalization* has entered modern parlance with increasing frequency, but in such varied contexts with such varied meanings as to render the term less than useful. All agree that it describes a perspective beyond the personal, local, and national, an awareness that human actions and institutions can have worldwide repercussions and implications. But which ones does globalization describe? Have borders been eclipsed and cultures merged in a peaceful rendering of the “global village”? Have peoples of the world been homogenized by drinking Pepsi and eating McDonald’s hamburgers while their children play with Pokemon Balls? Have transnational corporations succeeded in moving production at will to exploit the cheapest labor on the planet to manufacture their goods for ever-expanding world markets? Have nation states begun to hand over their dominion to overarching world governance? Is Western culture threatening to destroy indigenous or less dominant cultures through its control over media and commerce? Is there an accelerating sense of interconnectedness among people based on knowledge of the earth as a single ecosystem?

The answer to all of the above is a qualified yes and no, which only adds to the confusion surrounding the term *globalization*. Most commonly people use it to describe economic globalization. Since at least the Middle Ages, the system of market capitalism, or the pursuit of expanding markets and cheap labor beyond borders, has been the standard *modus operandi* for companies and enterprising individuals. However, the accelerating pace of modern life, with electronic movements of capital, instantaneous worldwide communications, and overnight delivery of goods and services has made the global economy more transparently global and market capitalism more blatantly exploitative.

It is interesting to note that only recently has the noun *globalization* been added in Webster’s dictionary. Although our world is becoming globalized, the process is by no means as complete as the noun form “globalization” would indicate. Nation states and borders do still exist, different cultures maintain separate languages and distinct identities, and the world of most individuals is still ordered by their allegiances to specific regional and cultural values. Nevertheless, there is a greater awareness among people in most parts of the world that our political, economic, and social spheres are expanding and intertwining more than ever before. Perhaps it is the unprecedented scope and speed of the changes taking place that promotes the use of an all-encompassing term like globalization.

A working view of globalization comes from Professor Rudd Lubbers of Tilburg University, in the Netherlands. It is short and descriptive, yet sufficiently open-ended to include multiple perspectives, including the educational perspective: “such acceleration of becoming or making worldwide that it gives rise to a great many new phenomena.” Lubbers’s definition emphasizes the speed at which changes affecting the entire planet are taking place and the great number of new phenomena that result, influencing economics, politics, and society.

Our ability to conceptualize and manipulate global systems of information, commerce, and governance makes some new demands on human ingenuity, for the scope of the globalization project necessitates new ways of responding to common issues like security, resource management, and human rights. The call for more global-oriented school curricula that respond to these societal changes has been advocated in the scholarly and practical work of Alger, Cummings, Kolker, Lynch, Pike, Rasmussen, Reardon, Tye, and others; but colleges and universities and other important institutions in civil society have been slow to respond.

What Is Global Education?

Global studies (education) is an interdisciplinary approach to learning concepts and skills necessary to function in a world that is increasingly interconnected and multicultural. The curriculum is grounded in traditional academic disciplines but taught in the context of project and problem-based inquiries. The learner examines issues from the vantage point of the individual, the local community, and the nation and the world community. As social

conditioning, an essential component of schooling, global studies takes an international stance that respects local allegiances and cultural diversity while adhering to the principles of the United Nations Declaration of Human Rights.

There is, however, no standard definition among proponents of global education. The Center for Human Interdependence (CHI), an educational training program that emphasizes global awareness, begun in 1984 in Orange County, California, constructed the following working definition:

Global education involves learning about those problems and issues that cut across national boundaries, and about the interconnectedness of systems, ecological, cultural, economic, political and technological. Global education involves perspective taking seeing things through the eyes and minds of others, and it means the realization that while individuals and groups may view life differently, they also have common needs and wants.

John Dewey was possibly the most influential educator of the 20th century. Dewey was a progressivist, and progressivism was his movement. Progressive education included several components, one of which was the emphasis placed on the democratic educational approach, accepting the interests and needs of an increasingly diverse student body in an increasingly interdependent world. Therefore, with John Dewey as the intellectual powerhouse, we see in the 1920s the rebirth of comparative studies. In the 1940s, we see that global education was reclassified as intergroup education. In the 1950s, we observe more name changes to fit the times, those of area studies, race relations, and ethnic studies. In the 1960s, the changes continued, and we had peace and conflict studies, human rights education, international studies, intercultural studies, and open classrooms. In the 1970s, as the Vietnam War was ending, we witnessed the women's liberation and African American liberation blossom, both in positive and negative terms. In the field of education, this was reflected by introducing multicultural and environmental education. In the 1980s, reflecting the reality of world affairs, we see the introduction of global education and world studies. From the 1980s to the present, we see that the global education as well as multicultural education have remained constant in the historical context.

In the 21st century, global education needs to distinguish its agenda from the current buzzword concept "globalization," the forces of market capitalism, which tend to focus the discussion on global economic systems and information technologies. From a pedagogical standpoint, economic prosperity and technological progress are part of a broader emphasis on planetary interconnectedness, interdependency, and sustainability. Key concepts in global education include human rights, environmental responsibility, cultural studies, and sustainable economies. Global education views national politics and transnational economic policies with an eye toward international accountability. It stresses the role of global ethics in shaping humane, environmentally sound attitudes toward a world as a single ecosystem, and it teaches that a global conscious citizenry can effectively overcome such problems as climate changes, ocean pollution, and resource depletion with ingenuity, leadership, and cooperation.

The emphasis in global education on human rights awareness, environmental studies, cultural understanding, and sustainable economies addresses the multiple concerns in our "globalized" world. Global education views national politics with an eye toward international accountability, which must be governed by a shared international sense of global ethics. This ethic can be used to govern socioeconomic decision making based on a system of universal values found in the United Nations documents of human rights, agreements of the Council of Europe Committee of Ministers, the proposals of Amnesty International and other nongovernmental organizations (for the realization of human rights), and the Earth Chapter project.

For advocates of global education curricula in schools, it is particularly important to enter the current debates over globalization and to articulate where the aims of global education overlap with some of the arguments that have been discussed. Schooling will inevitably reflect the cultural biases on which it is established, but as a general rule, global education aims to:

- Find a cross-cultural foundation for knowledge and human values
- Refine understandings of globally applicable ethical attitudes
- Consider how international organizations might affect national political and economic decisions

- Foster a global civic culture with a capacity for altruism and empathy, one that encourages social action and community service

Much of current education planning is focused on preparing students for the increasingly interdependent world and the diverse societies they will graduate into. The need for educators to have a sound awareness of other nations and their social milieus, cultures, customs, political and economic processes, and education systems is now well understood by professional educators, parents, and policymakers. Accordingly, teacher education programs in colleges and universities around the world have responded by introducing courses of study and program components to help meet this need.

Such courses and program components fall under the generic heading of *global education* but may have different labels such as *global comparative education* or *comparative education*. Postsecondary education has indeed reacted to the globalization phenomenon in a way that seeks to use the technological, economic, social, and political developments of recent decades to develop a shared vision of global responsibility and economic sustainability.

The value and utility of global education in education is that there is a sense that current international events are such that all societies and their citizens must become very knowledgeable about the world beyond their national borders. Usually, this imperative is cast in economic terms. Business and political leaders constantly warn us that the world's economies and financial systems are incredibly interconnected and our material well-being is dependent upon professionals and workers who have a sophisticated knowledge of this new global economy.

As we are at the beginning of the 21st century, we simply cannot afford the luxury of parochialism. There is no place to hide; the world is such that our professional, political, economic, social, cultural, and moral decisions and actions are intimately tied into new global realities. We must possess the knowledge and skills to act wisely and prudently. Unless people are able to grasp issues and events well beyond their homes and national borders, they will not be able to anticipate, understand, and intelligently respond to such events. The 21st century demands sophisticated citizens who are competent to deal with rapidly changing realities. In other words, as much as we may wish to, we cannot turn

back the clock to the days when family and local community to a large degree defined our values. Rather, the more complex and cosmopolitan viewpoint of the urbanized world traveler must merge practical and parochial concerns of the subsistence farmer: Both can play beneficial roles as global citizens. The answer may lie in integrating community-based values into the large-scale social institutions that currently govern our lives and allow us to conceive of a unified planet.

Another major rationale for global education switches our focus from the global to the local. That is, as teachers both at the secondary and postsecondary levels, we would want to be the most competent professionals that we could possibly be. To accomplish this, educators, and educational professional associations cannot limit themselves only to the knowledge and experience that local practitioners and education systems possess and generate.

Global education is schooling in all its aspects. Pedagogical strategies, curricular content, evaluation, classroom management, organization, and administration are conducted in fundamentally different ways around the world. Research into how children learn, what constitutes "best practices" in pedagogy, and how schools serve social and class interests is being conducted in many societies and in many different national and cultural contexts.

All around the world, educators, departments of education, education research institutes, professors of education, and others are working conscientiously to produce pedagogy, curricula, and diagnostic tools to better serve students, parents, society, and the teaching profession.

Courses in global education tend to fall into two general categories: survey courses and courses dealing with specific issues. Survey courses have three basic objectives. First, they seek to introduce students to the field of global/comparative studies in education. Students begin to learn about the nature of this interdisciplinary field, to appreciate its value, significance, and relevance, and to understand how global/comparative studies are pursued. Second, examinations of selected countries are undertaken as case studies. These case studies provide the database and substantive content for the third learning objective: comparing national systems of schooling; discerning common themes and trends; appreciating differences; understanding problems and controversies; and drawing conclusions, insights, and lessons.

A second category of courses focuses on specific issues in contemporary schooling, examined in an international context. In such courses, pressing issues in education are illuminated through an examination of how they are manifested in and grappled with in different societies and different national contexts. The scope of issues addressed by the current literature is quite remarkable; for example, equality of educational opportunity; educational achievement; evaluation and examinations; the treatment of minority groups; women in education; formal, nonformal, and informal education; delivery modes; teacher training, certification and supply; citizenship education; politics, ideology, and schooling; language and literacy; schooling and the economy; education, modernization, and development; education reform; accountability; effective schooling; school administration and governance.

The Development of Global Perspective in U.S. Education

Global perspectives in education is not a new idea. While efforts in this direction can be traced in earlier history, World War II was something of a watershed in its development. After the war, a widespread movement began around the world to foster education for “world understanding,” with the purpose of preventing a third world war. Children’s books in war-torn Europe, Japan, and the USSR featured peace and anti-war themes and empathetic stories about children of other lands.

In the United States, the Cold War chilled and slowed the movement for a time, especially in the 1950s, when McCarthyites saw “communism” behind every effort to increase international cooperation. But even in this climate, some educational leaders foresaw that the United States could not remain isolated forever from the rest of the world and that “international education” was in the national self-interest. The Soviet launching of Sputnik in 1957 was a spur not only to improved science education but also to increased pressure in the United States for international education. A year later, Congress passed the 1958 National Defense Education Act (NDEA). Under Title VI, it mandated the teaching of foreign studies, languages, and cultural understanding. However, practice did not match preachment; allocations were minimal. Years of effort followed as groups of educators and others in the United States pressed

for congressional support for substantive international and global education programs. Then, for a time under the Carter administration and the leadership of Ernest Boyer as Commissioner of Education, major breakthroughs seemed imminent. Boyer wrote:

Education that fails to acquaint students with their dependence on their fellow [humans], or with the fragility of human life itself on a planet besieged with burgeoning population and dwindling resources, is not essential education; it may be largely irrelevant data exchange.

In this period, 14 states adopted global education guidelines or programs. And although the notion of global education came under fire in the Reagan administration, there is now growing support among some United States business and educational leaders.

But even among those who do accept the need for global education, there is no widespread agreement on its definition, purposes, or objectives. Phrases such as “education for world understanding”; “intercultural,” “international,” “global,” or “foreign affairs” education; “global perspectives in education”; “transnational” or “planetary” perspectives; or “education for spaceship earth” are used interchangeably, even by professionals, blurring important distinctions. This ambiguity may be symptomatic of the new and tenuous nature of thought in the field and of the different emphases of different persons and institutions at a given time.

The various terms also represent a certain historical development, with “global,” “interdependence,” “transnational,” “planetary,” and “spaceship” references emanating in part from the new vision of the planet from outer space, in which national political boundaries were seen as artificial human creations, the real subject being the life and functioning integrity of the planet as a whole. Even here, debates regarding terminology ensued, with some concerned that words such as “global” and “spaceship” were too mechanical and homocentric, and others that “planetary” seemed to obscure the significance of human activity and cultural difference.

Perhaps most important, the different terms are symptomatic of changing—and sometimes conflicting—worldviews or paradigms. For example, phrases such as “foreign affairs” or “international” education suggest a state-centric vision in which the major actors are seen as governments, usually from the

perspective of how one's own national interest is served. In contrast, terms such as "global," "planetary," "transnational," or "interdependence" suggest a frame of reference in which variety of actors—economic, environmental, cultural, and people's movements as well as governmental—are considered for their impact on the world as a whole. National interest here is seen as inseparable from world interest.

However, such distinctions remain largely theoretical because of the lack of consistency in their use. In a period of competing worldviews, the more interesting and significant question is not what terms are being used, but: What is the underlying vision and purpose of education? And how will it affect our children and the people and world of tomorrow? Even the sharpest critics concede some need for "global education"—but what is really at stake here is not *whether* global education is needed, but *what* will be its underlying purpose?

Three Views of Global Education

View 1: Win the Superpower Contest

This view merges from a bipolar vision of the world that assumes that the most important fact of life as we approach the 21st century is the ideological conflict between the superpowers and their competition for world hegemony. One of its more prominent spokespersons is former U.S. Secretary of Education William J. Bennett. In his December 5, 1986 speech to the Ethics and Public Policy Center Conference, Bennett said:

Nowadays we are global power. We have global responsibilities, and international politics have a more pressing claim on our attention than ever before. We need to know—and pass on to our children—as much about the world as we possibly can.

What is it that should be passed on? In Bennett's view, "the central fact of today's political world is the defensive opposition of the United States and its democratic allies to the Soviet Union and its empire." After criticizing other approaches to global education, Bennett suggested that "global education properly understood" should include "geography and foreign languages, some foreign literature, and a lot of European history." But most important, our children should know first about themselves, about American literature and American history and American democracy.

What are its basic elements, its fundamental ideas? What are the values necessary to sustain it and the conditions for its success or failure?

And then they should know about totalitarian/theocratic regimes. What are their ideological roots? How have they acted in the past? And how do they act in the present, toward their own people and toward other nations?

And, of course, our students should know about the graduations of social, political, and economic arrangements in today's world between the few islands of the despotic, dictatorial, and theocratic countries and the vast encroaching ocean of the free and the democratic nations.

Finally, our high school students should learn about the key events of the last 60 years, particularly after the events of September 11, 2001, which have shaped relations between the United States and the Muslim world.

I would agree that all young people, from whatever nations, need to learn their national histories and how to be effective participants in their societies. They also need to distinguish between various forms of governance and to uphold basic human rights. But these are only starting points. A limitation of this approach is that it is *not particularly global*. It provides little understanding of other nations or cultures or of the deeper life processes of the planet. In its most benign form, it is an incomplete education—inadequate preparation for life in an increasingly interdependent world. Taken to extremes, it could lead toward fascism.

View 2: Win the Global Economic Contest

A second view of the need for global education in the United States emanates from international economic competition. In this view, the most important fact about today's world is not superpower competition, but the *emergence of one world economy*—global capitalism—and shifting centers of economic power within it. In the United States, this shift has the potential power of a Sputnik II in reshaping the purposes and direction of education, except that now, the major competitor concerning national leaders is not Russia or Japan, but the European Union. The possibility of the United States losing its economic leadership to the European Union, is having the United States looking to European education for clues to economic sustainability.

Not only Japan and Korea but also Hong Kong, Singapore, Taiwan, and the European Union have rapidly been gaining economic ground. Together, they represent a shift of economic power away from the West toward Asia. This carries not only economic importance but also potential significance with respect to political, cultural, military, and other forms of power in the future.

In the 1950s, the United States enjoyed a trade surplus; by the 1980s, it was experiencing chronic trade and payment deficits. The 1990s were healthy economic years for the United States. The country managed to eliminate the trade and payment deficits, but as the United States entered the 21st century, economic uncertainty coupled with the events of September 11, 2001 managed to reverse the American economic forward momentum to a crawl. Thus, in contrast to the “peace” focus of international education efforts after World War II and the military security goals that characterized the post-Sputnik emergency passage of the National Defense Education Act in 1958, some U.S. leaders now see the fundamental purpose of international education as helping to maintain U.S. economic strength.

With this in mind, when Congress decided in 1980 to make the Title VI NDEA international education programs part of the “mainstream” Higher Education Act, the strong national security rationale for these programs was augmented to include not only military but also economic security. A special business and international education provision was added to establish “export education programs,” among other things. Congress stated:

1. The future economic welfare of the United States will depend substantially on increasing international skills in the business community and creating an awareness among the American public of the internationalization of our economy.
2. Concerted efforts are necessary to engage business schools, language and area study programs, public and private sector organizations, and United States business in mutually productive relationship which benefits the Nation’s future economic interests.

The relationship between education and economic security was underscored by the National commission on Excellence in Education in its 1983 report *A Nation at Risk*, which stated that since “our once unchallenged preeminence in commerce, industry,

science and technological innovation is being challenged by competition throughout the world,” a revolution in U.S. education is called for.

The Southern Governors Conference also addressed the problem of “international illiteracy” in the United States and its negative effect on U.S. ability to compete in the international marketplace. The conference’s advisory council, made up of leaders from business, education, and government, issued a no-nonsense report in November 1986, which came right to the economic point:

Americans have not responded to a basic fact: the best jobs, largest markets, and greatest profits belong to those who understand the country with which they are doing business. . . .

We operate in a global economy. There are no more guaranteed markets for our goods. We must compete—and to compete we must be able to communicate. . . . We cannot trade goods or ideas unless we understand our customers and they understand us.

The advisory council’s recommendations for redressing the problem included increased emphasis in the schools on geography, international studies, and foreign languages; “sister-school” programs abroad; and teacher and student exchanges. They also recommend special educational programs and assistance to businesses, including programs on languages, foreign business practices, and cultural training.

View 3: Persons, Peoples, and Planet

It is clear, then, that when the pocketbook is affected, international or global education suddenly takes on a pragmatic importance that the purpose of peace alone could not give it. One can be grateful for increased U.S. interest in these aspects of global education—and yet sad, too. Certainly, economic strength and well-being is an important objective for all societies: How do we define it? And what is a truly global perspective in education?

As I look at the picture of the words in the above two approaches, I ask: What is the future of our children?

Africa (and Latin American, Asian, the Middle East) seems not to be included in either approach—except for a potential source of resources and markets.

Are our children to be educated to use their global competencies to take all they can from the world without giving to it? Are they to be educated to be cast in a global economic machine—to learn each other's languages only so the corporations they work for can get richer? What of their lives, their growth in their communities and cultures, the human hearts, their humanness?

And who speaks for the earth? What languages do we need to learn to understand our one earth better, with its limits and possibilities; to understand that in the end, all we really have is the earth—the source of our health, wealth, and wisdom?

What Are the Right Questions?

Approaching the global education debate from the third viewpoint, we must therefore start by asking ourselves: Have we even begun to *ask the right questions* about the kind of education we need for the future?

Today, we have new powers over life and death never dreamed of by our ancestors—but we have no idea how to use them wisely and well. We who are from the earth and of the earth cannot determine the next states in the earth evolution. We can intervene in the DNA—the delicate genetic coding that has built up through eons of natural selection. We can create new species test tubes. We can cause millions of plants and animal species to go out of existence—a part of the earth, ourselves, of the divine, lost forever. And we can through our human decisions render this planet uninhabitable for our unquestioning assaults and our weapons of mass destruction.

Such powers over life and death were in the past ascribed only to God. They demand of us that we become more morally mature, more deeply attuned to the life processes at work on the planet and that we assume adult responsibility for the future of the earth and the future of ourselves and our grandchildren.

Until we ask the right questions, how can we help our children learn to find the right answers? Acid rain, CO₂, deforestation, nuclear terror, hunger, overpopulation, alienation, despair, and terrorism—these challenges arise from our past failure to ask the right questions about education and our future together on the earth. Can such challenges be the starting place now for our shared journey into the future? By the very process of taking responsibility

for finding solutions to these common threats, can we become more truly human and more truly a human community?

I believe what we need to know *already exists* among us—in our minds and hearts and deepest yearnings—and that we need to begin to plumb our own depths for insight. We can begin by asking about our children. What would we want them to know if they were the ones to determine our fate and the fate of the earth?

Would we not want them to have a deep understanding and appreciation of their shared evolutionary past—the story of the earth, of its creative life forces, of human becoming, and of the common human subsistence in that one earth—as well as of their more local and distinct social, cultural, economic, and political roots? Would we not want them to understand the increasingly interdependent nature of the world and to learn how to take a creative and responsible part in its life? Would we not also want them to understand how their choices will affect us and therefore how to choose wisely, not only on their own behalf but also on ours? And would we not want them to be aware of the future and the way in which their choices will dramatically affect those yet to come?

What of their own personhood? What would we want them to experience as they go through life? What of laughter and joy, friendship, sharing, struggle and pain, celebration, community, beauty, empathy and compassion, meaning? We see so many youths alienated, on drugs, killing themselves one way or another; what do we want for these newborns? This too needs to be accounted for in our educational vision.

If we knew these babies held our future and the future of the earth in their hands, what values would we want to guide their decision making? Only the maximization of their own profit? Or would we want them to know how to create and maintain the conditions for peace, freedom, human rights, social justice, and ecological balance—and how to think critically, resolve conflicts, and solve problems creatively?

The central paradox in education is the fact that the millions of babies born this year do hold our future and the earth's future in their hands, even as we who nurture and educate them, by the very way we do so, will be shaping theirs. By the educational legacy we give them, we will be preparing them not only for

the future we hope they will have, but also for the future they will make for us.

Thus, the axial question as we go into the future is: "Education for what?" What will our children need to know, not only to survive in the interdependent world we are entering, but to become more truly human in its midst, more truly human community? It is the mission of every educator to struggle with these questions in our minds and hearts as we confront the most awesome task of nurturing and educating the world's children.

Finally, we need teachers who understand that society is inside all of us and all of us are inside society. We need teachers who are aware that unquestioning docility and compliance will pose more serious threats, anger, and turbulence in our world. We need teachers who recognize the value of the United Nations organization and its firm standing on humane principles against the power of totalitarianism. We need teachers who see themselves as agents of change, rather than defenders of the status quo. We need teachers who will commit themselves to the promotion of building global goodwill and to the elimination of all those cultural, religious, and traditional practices that alienate and dehumanize all of us. History tells us that we should have done more than train or teach others to think and feel in morally and politically adequate ways. It is never too late.

CULTURAL CONVERGENCE

Cultural convergence takes place in a society almost inevitably if two or more groups are brought together in close proximity. It can occur whether the social groups are equal or whether one or more are subject to a dominant group. This is the social atmosphere in which voodoo arose in the Western Hemisphere. When the slaves from Africa were brought across the Atlantic Ocean in unknown thousands, they brought with them their ancient religion, which would be their only source of security in a frightening and very hostile world. Historically, it is believed that the religions from the Yoruba region, now part of Nigeria, and the Congo, as well as today's Benin and Togo, became the source for what would become the New World adaptation of the African belief system: voodoo.

The slave masters hated and feared the ancient African beliefs because they provided a way for slaves to retain their ethnic and cultural identity on the plantations. Any slave found to be practicing voodoo, or Voudun as it is properly known, would be executed, sometimes by being burned alive. To avoid such a ghastly fate, practitioners of voodoo embarked on what was known as *syncretism*, or the

conscious grafting of their African beliefs onto the Roman Catholicism of the Caribbean Islands, which was their first American home. (The first Africans would not be brought to the North American mainland until in Virginia in 1619). In French-speaking colonies, the syncretism gained its more commonly known name: voodoo. However, in the Spanish domains, it would become known as *Santería*: literally, the worship of the saints. To make the fusion complete, the native practitioners appropriated Roman Catholic saints to stand symbolically for their own deities, which they could no longer openly worship. For example, the god Dambalawedo took on a new personification as St. Patrick, since Dambalawedo was a god associated with snakes, and St. Patrick was believed to have driven all snakes out of Ireland.

Gradually, Whites became devotees of voodoo and Santería as well, a unique example of cultural convergence that flourishes today. Few of the spectators—and perhaps not more of the participants—of the Mardi Gras celebration held each year in New Orleans on Fat Tuesday, the last day before the beginning of Lent, probably know that part of the celebration's origins stem from the frenetic voodoo dancing that took place more than 200 years ago in the city's Congo Square.

— John F. Murphy, Jr.

VANISHING CULTURES

As globalization increasingly becomes the battle cry of the 21st century, the West is not always aware of the threat this process is posing to thousands of cultures across the world. Anthropologist Wade Davis has warned that what he calls "ethnosphere," the wealth of human diversity and the potential of traditional cultures to teach about different ways of living and thinking, is continuously eroded and homogenized, and that such erosion will diminish us all. "The human imagination is vast, fluid, infinite in its capacity for social and spiritual

invention," Davis argues, and reminds us that "there are other means of interpreting our existence, other ways of being" different from ours. Cultures do not vanish through spells. Their disappearance has often a material and economic base. As a 2001 *National Geographic* article put it, "Can dugout canoes and medicinal herbs withstand the cultural muscle of jets and cola drinks? About 300 million people in at least 5,000 distinct indigenous cultures still hold to their roots. But governments coerce minorities to modernize and join mainstream society, and economic interests appropriate their lands."

Global culture does not only entail multiculturalism and a hybridization of national cultures, as its supporters claim. As critics of cultural globalization point out, there is a darker side to this process, as cultural globalism destroys local traditions and regional distinctions, creating in their place a homogenized world culture. According to this view, human experience everywhere is under threat of becoming essentially the same. Local cultures are replaced by a uniform and single culture, often dictated by the same powerful corporations that control the global economy.

The link between the vanishing of a given culture and economic exploitation is well illustrated by the execution in 1995 of the Nigerian author Ken Saro-Wiwa. The poet had taken a leading position in the Ogoni people's campaign against the human, ecological, and cultural destruction of the Niger Delta due to Royal Dutch/Shell's oil drilling. A Nobel Prize nominee and the leader of the Movement for the Survival of the Ogoni People (MOSOP), Saro-Wiwa had blamed the Nigerian dictator General Sani Abacha for the murders and tortures of thousands of Ogoni to silence their exposure of Shell's exploitation of their land and consequent destruction of their culture. At his trial that would end with the death penalty, Saro-Wiwa told the court that "Shell is here on trial. The company has, indeed, ducked this particular trial, but its day will surely come." The Saro-Wiwa incident was a powerful catalyst for the emergence of antiglobalization activism, as it showed the interconnectedness between issues of social justice, environmental exploitation, labor policy, and destruction of local cultures. As Naomi Klein makes

clear, "In Saro-Wiwa, civil liberties came together with anti-racism; anti-capitalism with environmentalism; ecology with labor rights. The bright yellow bulbous logo of Shell, Saro-Wiwa's goliath of an opponent, became a common enemy for all concerned citizens. Appropriately, it was Saro-Wiwa's brother who summarized the multiple significances of the author's execution: "In this case, at the twilight of the 20th century, Shell has been caught in the triangle of ecosystem destruction, human rights abuse, and the health impairment of the Ogoni people."

— Luca Prono

GLOTTOCHRONOLOGY

Glottochronology is a method that tries to calculate when two languages separated in the past. It is analogous to a kind of linguistic Carbon-14 test, but it usually cannot give absolute dates. The later term *lexicostatistics* is often used synonymously with glottochronology, though occasionally it simply refers to any kind of statistical comparison of lexical items from two languages.

It is obvious that languages change over time. Consider the opening lines of this poem by Chaucer written circa 1360. (The spelling has been standardized, and a modern rendition given to the right):

Almightly and all mercy-able queen [Almighty and merciful queen],
to whom that all this world fleeth for socour [to whom everyone in the world runs to for help],
to have release of sin, of sorrow, and teene [for release from sin, sorrow, and hurt],
Glorious virgin of flowers flower [Glorious virgin and flower of all flowers],
To thee I flee confounded in error [To you I come, confused and in error].

Even though this poem was written almost seven centuries ago, it is no doubt transparent to any native English speaker today, and only a few archaic words

are found. However, if we go back another few hundred years to Old English, things begin to look more and more like a foreign language as more and more of our familiar words drop out. Proponents of glottochronology argue that we might be able to measure the time depth of languages if we examine this rate of disappearance.

The glottochronology project rests on a number of assumptions. The first is that some words are more stable than others. Thus, an examination of basic core vocabulary will be more reliable than words that are more likely to change. There have been several proposed lists, based on several criteria, but a 100- or 200-word list is most commonly used. It includes terms referring, for example, to body parts, numbers, pronouns, and universal geographic features.

The second major assumption is the rate of change—that is, the loss of basic cognates (forms that have a common historical origin)—is the same for all languages at all times. Early proponents like Robert Lees and Morris Swadesh, comparing languages for which historical time depths were known, like the divergence of the Romance languages from Latin, conclude that anywhere from 80% to 86% would be retained over a thousand years. Using languages for which the time of separation was accurately known, they proposed the following logarithmic formula:

$$t = \log c / 2 \log r,$$

where time depth (in years) is represented by t , c the percentage of cognates shared between the two languages in question, and r the assumed retention rate (percentage).

As an example, we might compare five modern words from German and English, all core vocabulary items:

animal (*Tier*)
 four (*vier*)
 head (*Kopf*)
 I (*ich*)
 sun (*sonne*)

We find 60% agreement, as two pairs (animal/*Tier* and head/*Kopf*) do not appear to be related. If we assume that languages change at the rate of 85%

every 1,000 years, after looking up the appropriate logarithms, the above formula gives:

$$t = \log(60\%) / 2 \log(85\%) = -.511 / 2 \times -.163 = 1561$$

In other words, English and German diverged 1,561 years ago, around the year 400 CE.

Glottochronology was been used to track the time frames of many languages and families, from Native American languages, the languages of the Pacific, to Indo-European. Thus, for at least the more modest goals of obtaining relative dates of separation or for looking at languages within specific families, glottochronology seems to have proved it usefulness.

However, there are at least five important criticisms—or limitations—that might be leveled at glottochronology, both at the level of assumptions and practice. First, the list, whether the 100- or 200-item variety, invariably is not culturally neutral. Words for sun, moon, or certain colors, for example, no doubt carry varying symbolic weight across languages. Second, the method looks only at cognate lexical items and does not include an examination of pronunciation or grammar or changes in meaning over time. Third, it ignores borrowing and language contact, and this could easily skew results. For example, anywhere from 5% to 10% of the daily vocabulary items used in Japanese may come from English, including words for numbers and colors. Thus, a lexical statistical analysis might suggest that Japanese and English are more closely related than they actually are.

Fourth, it is not clear that the rates of retention are the same for all languages. Nor are we sure that even a single language will change at the same rate throughout its history. For example, the rate of change of English on a 200-word list is about 76% per 1,000 years, as is Coptic. However, German is 85%, Chinese 79%, and Greek 83%. But some languages are more retentive, such as rural Icelandic's 97% and Armenian's 94%. However, there are also less retentive languages, such as East Greenlandic, which appears to only hold 34% of its vocabulary over 1,000 years.

Finally, because of the nature of logarithms and the size of the word lists, the estimations tend to get more mathematically imprecise the further back in time you go. In fact, there is even a kind of linguistic "event horizon" (like that surrounding a black hole in physics, from which no light or information can escape), beyond which no comparisons can theoretically be made. This is around 25,000 years of separation

(though even the most ardent glottochronologist would probably not trust figures past 10,000 years)

Because of these difficulties, there have been many critics of glottochronology, some particularly harsh. For example, the noted structural linguist George Trager (1972) claimed that in its enthusiastic and polemical history, the mathematical basis of glottochronology has proved untenable "and the supposedly 'acultural' and universally usable set of basic vocabulary . . . is, anthropologically speaking, a chimera, and is often unuseable. . . . Where it has been taken seriously, it has sometimes led to ridiculously long or short periods of separation . . . [which are] just as likely to result from chance resemblance as a real relationship" (pp. 175–176).

Despite these attacks, there has been renewed interest in glottochronology in recent years. Dyen, Kruskal, and Black, in an exhaustive lexicostatistic study of the Indo-European family, found that glottochronology reflects the generally accepted language classifications made by other means, suggesting that the method may be more accurate than critics suppose. Various new methods of constructing phylogenetic trees (as in biostatistical research) have been added to glottochronology's arsenal, so it "may be that the 21st century will see increasing application of these methods in work on language prehistory" (Wang, 1994, p. 1450).

And when there are few other avenues of investigation open, sometimes only glottochronology can offer insights. For example, Edda Fields, a social historian of Africa, reconstructed the early history of the coastal Guinea-Conakry area with the help of lexicostatistics, as there were no good methods of dating oral narratives and no written documents before the entry of the Portuguese in the 15th century. She examined how rice-planting vocabulary was borrowed among the local languages to examine lines of culture contact, trade, and technological innovation. She used glottochronology to establish a tentative history of the Guinea coast, concluding that coastal speech communities have not migrated very far from their present-day locations, thus giving a picture of a settlement pattern very different from oral narratives that tell of the ancestors migrating from the interior seeking to grow rice. In the absence of other evidence, this may be the only resource we have to find out about this important, but largely unknown, period of African history.

GLUCKMAN, MAX (1911–1975)

The founder of the Manchester School of Social Anthropology, British born Max Gluckman completed his PhD at Oxford University in 1936. His role as director (1941–1947) for the Rhodes-Livingston Institute helped him to later establish the Rhodes-Livingston Institute as a field research site for a great deal of the work conducted by the Manchester School. Upon leaving the Rhodes-Livingston Institute, Gluckman became a lecturer at Oxford University. In 1949, he began his tenure at Manchester University and worked there until he passed away.

Gluckman is known for his studies on legal systems in traditional African societies. He focused on conflict and conflict resolution in parts of colonial Africa. Gluckman also advocated an anticolonialism stance and was against other forms of social injustice, including racism and classism, at a time when it was not particularly fashionable to do so.

Gluckman's anthropology was viewed as being unconventional by many outside of the Manchester School, at least partially because of his loyalty and dedication to the Manchester United soccer team. At the time, soccer was viewed as a game for the working class, and Gluckman viewed his department's support of the Manchester United as symbolic of his desire to lead the Manchester School in examining issues of oppression. Similarly, Gluckman emphasized the

importance of history in understanding contemporary societies and was careful to note that social anthropologists study modern societies in all of their forms, rather than viewing less developed societies as being prehistoric or even without history. The Manchester School was also known for having a Marxist orientation, and Gluckman encouraged his students to examine the historical and cultural contexts that influenced colonialism and its impacts on the colonized. As a result of Gluckman's concern for class issues, he tried to dissociate his department from British anthropology's historical connections to the upper middle class of England and the conservative ideologies by which it was influenced.

The Manchester School was at its peak from 1949 to the mid-1960s. The link between the Rhodes-Livingston Institute, which served as a field research site for the department during this time, and the Manchester School helped increase the productivity of the department. By the late 1960s, Gluckman began to withdraw from the department, and from 1971 to 1975, he served as a research professor at the Manchester School.

The numerous honors and awards earned by Gluckman include the Wellcome Medal and Rivers Memorial Medal, both awarded by the Royal Anthropological Institute; Mason Lecturer at Birmingham University; Manro Lecturer at Edinburgh University; Frazer Lecturer; President of the Sociology Section of the British Association for the Advancement of Science; and Member of the Human Sciences Committee of the Department of Scientific and Industrial Research of Her Majesty's Government. Gluckman's published work includes numerous articles, book chapters, and several books.

The belief in and attempt to manipulate the supernatural is widespread throughout humanity. Although the particular content of any people's religious or spiritual beliefs is dependent on their specific environment, lifestyle, social configuration, and history, the presence of spiritual or supernatural beliefs of some sort in virtually every society suggests that there may be a biological basis to the capacity to believe. Dean Hamer, a biologist and head of the genetic unit of the National Cancer Institute, claims that he has discovered at least one of the biological traits that fosters spiritual belief: a gene responsible for the production of one of the chemicals used to regulate emotion in the brain.

The God Gene (2004) is the title of Hamer's book presenting his research on the relationship between genes and spirituality. Specifically, the "god gene" refers to a particular variant of the gene that codes for protein VMAT2 (vesicular monoamine transporter 2), which plays a role in regulating levels of serotonin and dopamine in the brain. In Hamer's research, subjects whose VMAT2 gene contained either one or two molecules of cytosine generally scored much higher on tests designed to measure spirituality than those with only adenine in the same position.

In the course of research on smoking and addiction, Hamer administered a set of psychological tests to 1,388 subjects, including a set of questions based on the research of psychiatrist C. Robert Cloninger intended to measure a subject's self-transcendence. Cloninger's test measures three qualities: self-forgetfulness, the tendency to focus so intently as to lose track of the world around oneself; transpersonal identification, the feeling of connectedness to the universe and its inhabitants; and mysticism, the willingness to believe in things not approachable through reason. The test is intended to measure individual spirituality, divorced from the particular content of organized religious belief and orthodoxy.

Hamer's findings suggested a strong link between the presence of the cytosine variants of the VMAT2 gene and spirituality as measured by Cloninger's test. In test cases where one sibling had a cytosine variant, almost all scored markedly higher for self-transcendence than their non-cytosine-bearing siblings. After correcting for other possible influences, Hamer was convinced that a significant correlation existed. What

was left was to propose a mechanism by which VMAT2 might influence spirituality.

VMAT2 regulates the brain's use of monoamines, chemicals that play a crucial role in both motor control and emotional status. Among other things, monoamines and, thus, VMAT2 play an important role in coordinating the responses of the thalamocortical complex, responsible for perception and reflection, and the limbic-brain stem system, which produces emotional responses. During periods of heightened spiritual awareness, the Buddhist's meditative state, for instance, or the shaman's trance, the thalamocortical system draws more and more of the brain's blood flow and energy to itself, reducing the efficacy of the other centers of the brain in a process called *deafferentation*. One system affected by deafferentation is the part of the brain responsible for locating the body in space. As more and more energy is drawn by the thalamocortical system, these other parts of the brain send "panic signals" to the limbic system. The limbic system, in turn, signals the thalamocortical system, forcing it to draw even more energy to itself and setting up a feedback loop in the brain that produces a greater and greater feeling of detachment from or expansion beyond the body, a situation easily understood by most as describing a mystical experience. According to Hamer, those with the cytosine-holding variants of the VMAT2 gene might find it far easier to produce these kinds of feedback loops than those with the adenine-bearing variant, making them more open to mystical experiences.

Hamer himself notes that VMAT2 likely plays only a small role in spirituality, noting that spirituality is too complex a phenomenon to be reduced to a single gene or even a single neurological process. But even taking this into consideration, his work as it stands presents a number of difficulties. The first is the way in which he, following Cloninger, defines spirituality itself. Cloninger based his tests on a study of people he considered to be extremely spiritual—Albert Schweitzer, Mahatma Gandhi, Catholic saints, Buddhist monks—then chose the traits that he felt marked them as spiritual. It is hard not to wonder if his criteria might not represent a Western notion of individual spirituality that may not have much meaning in significantly different cultural contexts. Although the tests have been administered to Americans from a variety of ethnic backgrounds, the fact remains that they have yet to be administered outside of the United States and may only reflect

widely shared Western notions of spirituality. One has to ask if statements such as “I am fascinated by the many things in life that cannot be scientifically explained” or “I believe that miracles happen” would tell us anything useful about the spirituality of, say, an Amazonian hunter-gatherer or South Pacific horticulturalist.

Hamer’s hypothesis is further burdened by his uncertainty about how to weigh religious behavior as evidence. While at some points, Hamer insists on the noncommensurability of religion and spirituality, at others, he relies primarily on aspects of religious behavior, for instance, the role of religion in fostering and maintaining social solidarity, to ground his argument for the evolutionary importance of the god gene. In the first case, religion is opposed to spirituality, reflecting contemporary usage that associates “spirituality” with the individual and “religion” with the community. In the second, religion is presented as interchangeable with spirituality, so that the Venus figurines of Eastern Europe or the cave bear clans of Paleolithic France are seen as evidence of early human spirituality.

Ultimately, Hamer’s work presents more questions than answers. While his fundamental assumption—that regardless of what we believe, there must be some neurological structure within which believing occurs—is sound, his conclusions are broader than his research and evidence support. Basing universal conclusions about human biology on culture-specific evidence seems hasty and even dangerous. At best, he has produced a very preliminary hypothesis about one possible factor in spiritual behavior, one that demands much more rigorous testing.

Gods

The term *god* is very vague; its common uses include reference to an extremely wide range of sorts of thing, including living human beings (for example, the Egyptian pharaohs and the Roman emperors), humanlike beings with superhuman powers (for example, the Greek pantheon), and impersonal or even abstract concepts (for example, the Hindu Brahman). The aim of this article is to distinguish between some of the most important of these notions and to introduce some of the main ways in which different cultures have thought about and behaved toward their gods.

It’s perhaps worth pointing out at the beginning that the notion of gods is, while not independent of that of religion, certainly not coextensive with it. It’s even more difficult to give a single, universally accepted definition of *religion* than to do so for *gods*, but few would deny that it’s possible for a religion to do without gods (as, for example, do many forms of Buddhism) and for someone to believe in the existence of gods while engaging in no religious practices or committing herself or himself to any particular set of religious doctrines.

Types of Belief

A narrow, technical use of the term *theism* picks out the belief that god continues to be active in the world, as opposed to *deism* (common especially in 18th-century Christianity). Deists believe in the god of *natural religion*—that is, religion based solely on the use of human reason—and typically hold the view that god set up the world to be governed by perfectly designed laws and then stepped back and let it run according to those laws, taking no further part in its affairs. In what follows, however, the term *theism* will be used in its broader, more everyday sense, referring to any belief in the existence of a god or gods. There are many types of theistic belief, though the following are the most common.

Polytheism is the belief in and worship of more than one god. It seems that most if not all religions were originally polytheistic, the gods usually being seen as powerful versions of human beings or as anthropomorphized animals, heavenly bodies, or other natural phenomena whose origins predate humanity and who often figure in creation stories.

Surviving polytheistic religions include Shinto, Vodoun, and certain types of Hinduism. Some non-Christians, especially Jews and Muslims, consider the Christian doctrine of the Trinity to be polytheistic; indeed, Christian thinkers have also sometimes held this sort of view, most notably the Arians. The belief in just two gods is sometimes distinguished under the label *ditheism* (or *bitheism*); in most religions involving two gods, however, only one is worshipped—see below.

It should be stressed that mere belief in more than one god isn't enough to make a religion polytheistic in the strict sense; the issue of worship is also crucial. *Henotheism* is the belief in a multiplicity of gods but the worship of only one. The one worshipped god might be picked out because it is seen as being especially powerful or important, and this is sometimes labeled *monolatry*; some Christian sects take this view of the Trinity, holding that only God the Father should be worshipped, Jesus and the Holy Spirit being distinct and lesser gods. On the other hand, different cultures might be seen as having each its own god, so that though other gods exist, they are worshipped each by members of their own peoples (as appears to have been the case at one stage of early Judaism). The distinction between the two versions of henotheism isn't very clear cut, as most people consider their own culture superior to others, and in the same way are very likely to hold that their culture's god is more powerful or important than other gods. *Kathenotheism* is a similar sort of belief, but rather than worshipping one god throughout their lives, believers worship different gods at different times or in different places. Thus kathenotheism is a sort of serial henotheism.

Henotheism is to be found in narrower forms, especially *ditheism*, and can also develop into *monotheism*. Ditheists hold that there are two gods, usually one good and one evil; typically, the universe in which we live is thought to have been created by the evil god (hence the prevalence of evil in the world) and the good god to be involved in a battle with its evil counterpart; Zoroastrianism is an important example of this sort of belief. This is often, especially in later versions such as that of the Manichaeans, accompanied by the view that the material world is evil, while the spiritual world, good.

Monotheism is belief in the existence of just one god, but there are a number of very different sorts of belief fitting that description. The commonest sort of

monotheism is that found in the Abrahamic religions, such as modern Judaism, Christianity, and Islam. Believers typically hold that there exists a being that is the transcendent cause of the universe in which we live—that is distinct (or usually separate) from it—and that this being is worthy of worship. The god in which most monotheists believe is personal.

The main alternative form of monotheism is *pantheism*, the thesis being that god is the world and the world is god; thus everything that exists constitutes a unity, which is thought of as divine. This should be distinguished from *panentheism*, which is the thesis that the world is part of god (sometimes that it is god's body), but that god is more than just the world. The pantheist notion is rarely if ever of a personal god; indeed, its critics have often complained that the difference between atheism and pantheism is little more than linguistic. Pantheist beliefs have generally been restricted to philosophers and theologians, but panentheism has an important place in religions such as Judaism and (though to a much lesser extent) Christianity. Somewhere between standard monotheism and pantheism is the Hindu notion of Brahman—an impersonal, eternal, qualityless Absolute, which when qualified by qualities is the immanent and continuous cause of the universe.

Types of God

The concept of god with which most readers will be familiar is probably that associated with the standard monotheistic religions: an infinite being described as the omnipotent, omniscient, transcendent creator of the world. This notion is extremely variable, though, even leaving aside pantheism and panentheism. For example, the one god is sometimes thought of as a person and sometimes as an abstract existence; sometimes as eternal (that is, outside time) and sometimes as sempiternal (that is, in time but without beginning or end); sometimes as involved with the world and sometimes as detached from it. The single god of religions such as Christianity and Judaism is regarded by some believers as being less than infinite in its qualities—even as being imperfect. For example, process theology holds that god is “dipolar”—has two aspects or natures, one being transcendent, but the other being part of the world, suffering and changing with it.

Once we get on to the notions of gods found in nonmonotheistic religions, things become even more

varied. Clearly, such gods must be finite (as two infinite beings would limit and thus cancel out each other's infinity); they tend to be exaggerated versions of things existing in the natural world—most often humans or animals (or combinations) but sometimes inanimate objects or phenomena, such as winds, fire, or mountains. Even in nonmonotheistic religions that aren't henotheistic or kathenotheistic, there will often be preferences—either personal, or by sex, family, or caste—so that certain gods or groups of gods are worshipped more than or even instead of the other gods of the religion. This can be seen, for example, in Hinduism, with its many sects (perhaps mirrored in Christianity by attachments to various saints).

Attitudes To and Uses of Gods

Generally speaking, the attitude to gods is positive (partly as a matter of definition; a being who is regarded negatively is likely to be—though not inevitably—seen as something other than a god, such as a demon). However, the benevolence of few if any gods can be taken for granted, and worship in most theistic religions involves some form of bargaining, which most commonly takes the form of praise, appeasement, or petition. This is often bound up with another common use of the notion of gods: to explain natural phenomena (often including the very existence of the world, through creation myths). Thus the bargaining will frequently concern the averting of natural evils or the encouraging of natural goods; these can take the form of occasional events such as earthquakes, of regular occurrences such as the migrations of prey animals, the flooding of a tidal river or even the rising of the sun and moon, and of background conditions such as health and sickness. Similar activities can also be designed to ensure that one's actions won't provoke anger or retaliation or to ensure the success of a project. (This sort of bargaining activity can also take place with spirits other than gods, as in most animistic cultures.)

In fact, appeals to gods are rarely genuinely explanatory in form, though they may have the psychological effect of reducing or banishing puzzlement in the believer's mind. That's largely because they fail to offer an answer to the question, How did that happen? instead answering the question, Who did that? One important exception to this is the use of gods to justify or to explain religious and secular authority. Such justifications might involve the claim that a

ruler is a living god, that he (or more rarely she) is descended from gods, that he or she will become a god after death, or that he or she has either been given authority by a god or gods or is descended from one who has been given such authority. In Western cultures this last approach is best known through the doctrine of the divine right of kings.

Not all religious activity is concerned with bargaining, however; other purposes include praise, thanks, and reminding people of the existence and nature of the gods.

The Bifurcation of Beliefs

It's fair to say that, as cultures develop more critical and reflective thought about their religious beliefs, a split inevitably appears (and steadily widens) between the beliefs of ordinary people and those of the thinkers—philosophers and theologians. This normally involves a move from the notion of gods as personal—indeed, as more or less human, though exaggeratedly powerful people—to a more abstract notion of (usually) a single god, and then to a notion of god as some sort of idea or symbol, not literally real but important in some way. The notions of divinity (as well as of other aspects of religion) produced by this sort of theological development may be more consistent, but they're generally of little use for religious practice, nor do they fill the psychological roles played by more primitive notions; in cultures that have produced such thinking, therefore, the split is commonly not merely between philosophy and religion but between philosophy and theology on the one hand, and organized religion and ordinary beliefs and practices on the other.

VON GOETHE, JOHANN WOLFGANG (1749–1832)

Johann Wolfgang von Goethe was born on August 28, 1749 in Frankfurt a.M. Main and died March 22, 1832 in Weimar. He was a poet, playwright, and novelist but also a natural philosopher, scientist, and minister (*Geheimer Rat*) of the duchy of Sachsen-Weimar-Eisenach.

His parents—Katharine Elisabeth neé Textor and Johann Kaspar Goethe, a lawyer who held a property big enough to make a living—belonged to the Frankfurt bourgeoisie (*Bürgertum*). Goethe studied law in Leipzig (1765–1768) and Strassbourg (1770–1771), later working for a short time as a lawyer in Frankfurt a.M. and Wetzlar.

His first drama “*Götz von Berlichingen*” was published in 1773 and his novel *The Sorrows of Young Werther* (*Die Leiden des Jungen Werthers*) in 1774. The epistolary novel describes how a young man called Werther loses his heart to Lotte, who has already decided to marry another man, and ends tragically with the protagonist’s suicide. These two works, particularly the last, made him very renowned in Europe.

In September 1775, Goethe was invited to Weimar by duke Karl August, where he was to spend the rest of his life, apart from his travels. He soon became acquainted with Karl August, who appointed him as a member of Saxe-Weimar’s government in June 1776 and raised him to nobility in 1782. In 1784, he discovered the human premaxilla jaw bones (*Os intermaxillare*), but because all recognized anatomists (but for his teacher, Justus Christian Loder) denied his discovery, Goethe gave up and did not publish it before 1820. From 1786 to 1788 Goethe traveled in Italy, where he met many German artists (for example, Deutschrömer) and studied painting. He published his experiences in *Italian Journey* (*Italienische Reise*) in 1816. While in Rome he wrote *Iphigenia in Tauris* (*Iphigenie auf Tauris*), one of his most important dramas. In 1789, a son named August was born to Goethe and a woman he would marry in 1806, Christiane Vulpius.

In his work “Attempt to explain the metamorphosis of plants” (*Versuch die Metamorphose der Pflanzen zu erklären*, 1790), Goethe asserts that all plants developed by metamorphosis from one primal plant

Source: Courtesy, Wikipedia.

(*Urpflanze*). His major scientific work is the “Theory of Colour” (*Farbenlehre* 1805–10) in which he denies the ideas of Newton.

In 1796, Goethe published the epos *Hermann and Dorothea* and the novel *Wilhelm Meister’s Apprenticeship* (*Wilhelm Meisters Lehrjahre*). The latter is considered to be the most important German *Entwicklungsroman*, describing the intellectual development of a young bourgeois (*Bürger*) to an artist. The second part of this novel, *Wilhelm Meister’s Travels* (*Wilhelm Meisters Wanderjahre*), was published in 1821 and 1829.

Goethe’s friend Friedrich von Schiller, one of the most important intellectuals and authors of the age, died in 1805 in Weimar. One year later, Goethe finished his work *Faust, a Tragedy* (*Faust—Der Tragödie erster Teil*, published 1808), in which the scholar Faust sells his soul to the devil Mephisto. In return, Mephisto has to serve him until he is content and wants “the moment to stay.” Faust falls in love with Gretchen, who gets pregnant but kills the newborn out of despair. He tries to save her from execution, but Gretchen, feeling she has to pay for her sins, refuses to take flight. In *Faust II* (*Faust—der Tragödie zweiter Teil*, published postmortem in 1833), Faust experiences

the European history of ideas. In the end, he is mighty but blind and dies looking forward to eternal glory. Mephisto tries to claim his soul but is tricked by angels, and Faust finally attains salvation.

Goethe also wrote his autobiography, *Poetry and Truth (Dichtung und Wahrheit)*, and just as important as his novels and dramas were his lyrical works, from early poems such as “Prometheus” and “Roman Elegies” to his late poems, especially in “Der Westöstliche Divan.”

Goethe never had a homogeneous theory of the nature of humankind, but he did present a few main ideas to which he often referred. In *The Origin of the Species*, Charles Darwin calls Goethe one of the first who spoke “the law of compensation or balancement of growth.” Trying to discover the nature of humankind, Goethe considered both the results of his natural studies and his life experiences. Seldom does he refer to specific philosophers, although he presents the ideas of Spinoza, Rousseau, Herder, Diderot, Pico della Mirandola, Manetti, Kant, and his friend Schiller in his thinking. Theory unproved by data was mere speculation to him.

Goethe’s central aim in his research was to provide evidence for the primordial unity of all species. According to Goethe, they originated in one primal type of species. One of the missing links to this unity was found when Goethe discovered the human pre-maxilla jaw bones. Goethe believed that the highest creature in nature was man, in whom all natural laws of morphology are present at an enhanced level. A single individual cannot represent the original type of a species, but all individuals of one species can. One of Goethe’s famous remarks is “Only all humans live the human.” We must read Goethe’s literary work as explanation of his ideas about mankind. Faust is the paradigm of man in his quest for insight and creativity. He wants to enjoy all that is allotted to mankind as a whole. This immoderate desire cannot be fulfilled, finally leading to his failure.

There are five major constants in the human existence: individuality, polarity, aging, metamorphosis, and, finally, that human beings are an end in themselves.

According to Goethe, individuality distinguishes human beings from the moment of our births from every other human being. Polarity, the second principle, is the everlasting conflict of sublime and primitive, of nature and spirit or body and soul. Every period in a human life offers a unique range of possibilities not

present at any other moment. Metamorphosis is another central paradigm in nature and therefore also in humankind. Every being changes the world and is, in return, changed by it in an everlasting process. One of Goethe’s central metaphysical thoughts was that human beings can change themselves and react consciously, but, at the same time, we are still part of the wholeness of the world.

GOODALL, JANE (1934–)

Jane Goodall is a world-renowned primatologist who was born in London on April 3, 1934 to Mortimer and Vanne Goodall. Her family decided to move to England when Hitler began invading areas of Europe. She spent most of her childhood on the south coast of England in Bournemouth. She lived with her mother, her maternal grandmother, and sister Judy at the Birches. After high school, at age 19, she attended a secretary training school in London.

In 1956, a schoolmate invited Goodall to visit in Kenya. Goodall had dreamed of Africa since early childhood, possibly as early as 1 year old, when her father gave her “Jubilee,” a stuffed chimpanzee. After a few weeks, Goodall went to Nairobi to work as a secretary and arranged to meet Louis Leakey, who hired her as his personal secretary. Leakey soon invited Goodall to join him and his family for archaeological research at Olduvai Gorge. Leakey then gave her the opportunity to study the chimpanzees of Gombe, despite her lack of university education. He recognized Goodall’s potential, and it was her scientific naïveté that Leakey believed would give her an observational advantage leading to wonderful new discoveries.

Research with the Gombe chimpanzees began in July of 1960 with funding from Leighton Wilke of Illinois and later by the National Geographic Society and others. Goodall arrived in Gombe with her mother,

Vanne, two scouts, and their cook, Dominic. She had enlisted her mother's companionship because the British government did not like the idea of a young English woman alone in the jungles of Africa. During the beginning hardships of setting up the camp and working on getting the chimpanzees to accept her presence, Vanne was a comforting source of support for Jane. She stayed at Gombe with Jane for the first 5 months.

Leakey also did not like Goodall being alone at Gombe. He sent Hugo van Lawick, a filmmaker and photographer for *National Geographic*, to work with Goodall. They got along well and married in 1964. Goodall and van Lawick also had a child in 1967, Hugo Eric Louis. He is better known as "Grub." Grub stayed in Gombe with Jane when the couple divorced in 1974.

Goodall received her PhD from Cambridge University in Ethology, in 1965. She is one of only eight people to have earned this degree without first earning a bachelor's degree. Her thesis advisor thought her research was unprofessional, especially because she named her subjects. Goodall believed it was important to see the chimpanzees in an anthropomorphic light if she was to study their emotional lives.

In 1975, Goodall and the Gombe camp endured one of the most terrible hardships possible when four students working at Gombe were kidnapped. A ransom was eventually paid for their safe return. However, scandal and rumors regarding the situation followed Goodall for many years. For her own safety, it was 2 years before she was able to return to Gombe.

Also in 1975, Goodall remarried to Derek Bryceson, a politician, the only voluntarily elected White official at the time and former head of the national parks in Tanzania. Sadly, Bryceson died of cancer in 1980, after only 5 years of marriage.

Goodall has been the Scientific Director of Gombe Stream Research Center (GSRC) since 1967. Goodall's research at GSRC directly led to observation of many previously unknown behaviors in wild chimpanzees,

Source: Photograph courtesy of the Library of Congress.

including tool use. Among the most startling observations were of intracommunity infanticide and cannibalism in 1971, as well as intercommunity fatal violence as demonstrated by the "Four Years War" (1974–1977). During this period, Goodall observed one of the Gombe chimpanzee troops, the Kasakela group, systematically hunt down and terrorize a smaller splinter troop, the Kahama group, which had recently split from the others. Eventually, all of the members of the Kahama group were killed.

Other important observations made by Goodall include the discovery of elaborate courtship patterns, in which males force females to have exclusive relationships during the female's estrous cycle, the period when she is sexually receptive and fertile. These consortships occur in remote spots and last for days or even months. Also, in 1987 Goodall and her field staff observed an adolescent chimpanzee named Spindle adopt a 4-year-old orphaned chimpanzee named Mel. This was startling, because the infant was not a close relative of Spindle's and would have certainly died without the adoption.

In 1977, Jane founded the Jane Goodall Institute for Wildlife Research, Education, and Conservation (JGI), a global nonprofit organization now located in Washington, DC. Along with raising funds to further research at GSRC and other projects, JGI "advances the power of individuals to take informed and

compassionate action to improve the environment of all living things.” JGI also began Shoots and Roots, an international program for children that teaches conservation of all creatures.

Goodall has received a multitude of honors, which include the J. Paul Getty Wildlife Conservation Prize in 1984 and the United Nations “Messenger of Peace” presentation in 2002. In 2003, Queen Elizabeth II named Goodall a Dame of the British Empire, and she received the Prince of Austria’s Award for Technical and Scientific Research. As well as receiving honorary doctorates from several universities, Goodall has a list of publications ranging from her scientific research at Gombe to her personal biography.

Today, Goodall still calls Bournemouth home. She continues to travel the world lecturing and sending out a message of hope for the future of conservation of habitat and protection of the African great apes. Goodall is especially fond of encouraging young people to make a difference in the world. She created the Chimpanzee Guardian Project, which allows the public to contribute financially to the care of orphaned chimpanzees living in sanctuaries in Africa. Chimpanzee research and conservation efforts at Gombe continue and are largely carried out by local villagers who have been scientifically trained. The population of wild chimpanzees has declined drastically during the four decades of Goodall’s research. One of her resounding understandings is that it is the local people who must understand and care about conservation in order for efforts to be affective, be it in Gombe or elsewhere in the world.

JANE GOODALL

Jane Goodall is a naturalist, ethnologist, conservationist, and author who has revolutionized knowledge about chimpanzees and animal ethics. She was born in England in 1934. In 1960, after working in Africa with Louis S. B. Leakey’s research team as a secretary, she began a study of a band of chimpanzees in the Gombe Stream Game Reserve in Tanganyika (now Tanzania). For months, Goodall followed a band of chimpanzees, constantly studying them while moving ever closer to them. She recorded many behaviors that researchers had previously not seen.

Goodall’s legacy includes the very important discovery that chimpanzees are not strict vegetarians, as previously thought, but also eat meat. She found that they eat meat for a period and then return to a vegetarian diet for other periods. To get meat, they will sometimes engage in chimpanzee cannibalism. Goodall also discovered that chimpanzees will organize hunting parties. She was also able to describe chimpanzee “wars” between different groups of the primates. Goodall’s field observations contributed enormously to the understanding of the complexity of chimpanzee social order and hence shed light on human behavior.

Goodall also described the use by chimpanzees of small tools for foraging insects, especially termites from termite mounds. This discovery about chimps overthrew the older idea that only humans made tools.

Working with chimpanzees inspired Goodall to engage in conservation work to stop poachers from killing them for meat or taking baby chimpanzees to sell. To protect chimpanzees, she has promoted creating chimpanzee sanctuaries in the wild and improved ethical standards for the treatment of all animals in zoos.

Goodall’s legacy also includes numerous books for scientists, lay readers, and children. *In the Shadow of Man* and *The Chimpanzees of Gombe* have provided scientists with new knowledge. She has authored many children’s books in order to make young readers aware of animals in general and chimpanzees in particular. Her children’s books

include the “Family” series about a number of animals, including the *Chimpanzee Family Book*. In addition, she has published *Dr. White*, a book about the therapeutic play of a dog in a children’s hospital ward, and *With Love: Ten Heartwarming Stories of Chimpanzees in the Wild*, and *The Chimpanzees I Love*.

Goodall founded the Jane Goodall Institute in Washington, DC., to promote healthier ecosystems. Her “Roots and Shoots” program encourages environmental education for teenagers.

— Andrew J. Waskey

GOODE, WILLIAM JOSIAH (1917–2003)

“Si” Goode was born in Houston, Texas in 1917. He died in 2003, holding the position of Emeritus Professor of Sociology at Stanford University. In his career, he held many distinguished positions within academia, including his election as 63rd president of the American Sociological Association, in 1970. Goode earned a long list of academic awards, beginning with his career as a student. In 1994, he earned the William J. Goode Award, established in his honor. Goode published 20 books and over 80 articles. As a sociologist, Goode’s research focused on social organization and social structure. He contributed to anthropological literature in his cross-cultural analysis of love, marriage, family life, and divorce. He also contributed to sociological theory in his study of social control, violent force, and religion. Goode’s most widely recognized research, *World Revolution and Family Patterns*, was published in 1963. The data covered over a half century and over 50 countries. It called upon Goode’s mastery of nine languages to complete. Thirty years later, Goode published *World Changes in Divorce Patterns*, in which he introduced the conceptual basis for analyzing and predicting divorce patterns across the globe. He was particularly interested in the consequences of divorce for women.

Goode believed in the role of theory in scientifically generated knowledge. His contributions were greatest in the practice of middle-range theory and

the use of multiple research methods. While he was trained as a classic sociologist, Goode practiced rigorous anthropological methods. He introduced his students to systematic and comparative analysis of social structures and functions across cultures. He had an uncanny ability to make his work accessible to the very people he studied, a method typically attributed to anthropologists.

Goode was a distinguished success in all pursuits, both academic and personal. He left his PhD studies at Pennsylvania State University to enlist in the Navy during World War II. He served as a radarman on a trans-Pacific troop transport ship between 1944 and 1945. In 1946, Goode became an Assistant Professor at Wayne State University. He moved to Columbia University in 1950, where he earned tenure (1952) and was promoted to full professor (1956). At Columbia, he became quite active in the feminist movement as a scholar and an activist. He coedited *The Other Half: Roads to Women’s Equality* with Cynthia Epstein and worked with Betty Friedan as she wrote *The Feminine Mystique*. Goode joined Stanford University in 1977 and Harvard University in 1986.

Goode was described by friend and colleague Amitai Etzionia as “the man who studied with much gusto and to perfection, anything that sparked his interest, the list of which was very hefty indeed.” Si Goode was a fellow of the American Academy of Arts and Sciences. Referred to as a “renaissance man” by his friends and colleagues, Goode was internationally recognized as a scholar and a teacher. He served as a guest lecturer and visiting professor in many foreign countries. His legacy continues in the form of the William J. Goode Award, established during his lifetime, and the William J. Goode International Fellowship, which was established in his memory.

GORILLAS

The wild gorilla of equatorial Africa is the largest of the four great apes; the mountain subspecies was discovered in 1847 but first scientifically described in 1902. Until recently, this primate was thought to be a brutish and ferocious animal of the jungle. However, field studies have revealed that this huge pongid is shy, gentle, and introverted but curious, intelligent, and powerful.

In prehistoric times, wild gorillas ranged freely throughout central Africa. Today, however, this great ape is represented by only three geographically isolated subspecies: the lowland or valley gorilla of central West Africa, *Gorilla gorilla gorilla*; the slightly smaller highland or mountain gorilla of central East Africa, *Gorilla gorilla beringei*; and the lowland gorilla of East Africa, *Gorilla gorilla graueri*. The minor differences between the two major subspecies are that the mountain gorilla has longer hair (an adaptive advantage) and has a longer palate than the lowland gorilla and does not share its forest with chimpanzees.

Now a critically endangered species, the wild gorilla needs to be understood and appreciated in order to ensure both its protection and survival in captivity, as well as in its natural environment. It is estimated that fewer than 1,000 mountain gorillas inhabit the lush forest areas of central East Africa. Their ecological niche is gravely threatened by hunters, farmers, and poachers—thus the desperate plight of this mountain ape.

Source: © iStockphoto/Kevin Tate.

George B. Schaller, a zoologist, was the first scientist to seriously study the wild mountain gorillas in their natural habitat. His pioneering 20-month research project (1959–1960) remains a classic contribution to primate ethology. He has presented his important findings in two books: *The Mountain Gorilla* (1963) and *The Year of the Gorilla* (1965).

Gorillas are primarily terrestrial, quadrupedal climbers and knuckle walkers, living in the humid rain forests of Africa. In his extensive study of the mountain subspecies, Schaller concentrated on the ecology and general behavior of this remarkable great ape. His 466 hours of direct observation were made from the safety and viewing advantage of trees. Schaller was able to watch free-living gorillas wander through the dense jungle, forage on succulent herbs and vines (they prefer young secondary forest growth), groom and play, and build nests in the trees or on the ground. The zoologist observed no tool use, no meat eating, and no drinking of water. Both vocalizations and sexual behavior were infrequent. Of particular interest, however, is the gorilla's chest-slapping behavior—an elaborate sequence of nine distinct acts by a provoked gorilla in order to frighten away a threatening intruder, thereby preventing physical contact.

Despite his dedicated study of this wild ape for nearly 2 years, Schaller never made physical contact with these mountain gorillas. Yet this incredible feat was later accomplished by the remarkable primatologist Dian Fossey.

During 1967–1985, anthropologist Fossey lived among the wild highland gorillas of the Virunga Volcanoes in central East Africa. (The lowland or valley gorillas of central West Africa still await rigorous study.) Her research camp, Karisoke, was located in the ancient rain forest of Mt. Vasokie—a tropical world of jungle, fog, and mist in Rwanda near Zaire. Encouraged by anthropologist Louis S. B. Leakey, Fossey had followed gorilla groups on the ground in order to observe them at close range during their leisurely day-long search for food. Fossey was very successful in establishing a rapport with

these great apes; she patiently learned to imitate their feeding methods, general sounds, and basic gestures. As a result of her relentless efforts, these curious and gentle giants of the primate world had slowly accepted the anthropologist's presence. This acceptance allowed her to examine the uninhibited behavior of mountain gorillas under normal conditions in their natural range.

Fossey's more extensive long-term, close-range, more intimate study of the mountain gorilla had been a rich and rewarding experience for her and science. Unlike Schaller, she had actually made physical contact with this great ape—the first time a scientist had touched this pongid in its own habitat.

In the glorious rain forests, this magnificent great ape is a peaceful vegetarian and primarily a ground dweller. A nervous gorilla will hoot, mouth a stick or leaf, thrash branches and vegetation about, slap its chest, run sideways, and finally thump the ground with its palms. It may even bluff a roaring "charge" as protective action, if necessary. The pongid's alleged savagery toward humans is grossly exaggerated, for this fierce-looking and powerful ape will try to avoid physical contact with intruders. In short, unprovoked gorilla brutality is a myth.

Most gorillas live in small, stable, tight-knit, scattered groups that roam through the rain forests of central Africa and wander on the slopes of the Virunga Volcanoes. A social unit is dominated by the adult alpha silverback male. Other members include subordinate blackback males, adult females, juveniles, and infants. Protected by the dense jungle foliage and its huge size, an adult male mountain gorilla may live in an all-male small group or even as a loner. (Apparently the leopard, buffalo, and elephant are no threat to this great ape.) Each gorilla seems to possess a unique personality and a distinct voiceprint and noseprint. A gorilla's staple diet is primarily folivorous; it consists of fruit, bark, thistles, nettles, celery, blackberry leaves, gallium vines, and other wild succulents. In its natural environment, the mountain gorilla has never been observed eating meat, insects, or birds' eggs.

The gorilla is an intelligent animal, but in the rain and bamboo forests of mountainous central Africa, more fully developed mental capabilities and ingenuities probably would not have increased its fitness. Its awesome size and placid nature make it very difficult, if not impossible, for humans to train and manage this pongid. In zoos, the gorilla is prone to fatal pneumonia and tuberculosis, and therefore the artificial environment must be watched carefully.

Unfortunately, it is also very difficult to mate this great ape in captivity; gorillas require privacy and conditions similar to their natural habitat for sexual activity.

Fossey's research had added to the knowledge of the gorilla diet, feeding and grooming habits, and vocalizations. Her work was an outstanding contribution to ethology. Even so, the mountain gorilla still faces the grave danger of extinction. Civilization is now slowly engulfing the shrinking wild domain of this magnificent ape. The pongid's precarious existence is threatened by human encroachment. If serious measures are not taken, then this unique primate may vanish.

GORILLAS IN CAPTIVITY

Gorillas are the largest of the great apes. They exist in small numbers as at least three closely related subspecies: western lowland gorillas (*Gorilla gorilla gorilla*), eastern lowland gorillas (*Gorilla gorilla graueri*), and mountain gorillas (*Gorilla gorilla beringei*). They are all native to

central Africa. Gorillas were not identified as a separate species until 1847.

The first extensive description of gorillas to be published was by Paul Du Chaillu (*Explorations in Equatorial Africa*, 1861). Du Chaillu described several gorilla hunts where the hunting party encountered "ferocious" gorillas. Fieldwork by George B. Schaller, Dian Fossey, and others in the 20th century demonstrated that Du Chaillu misunderstood the ferocity of gorillas; their ferocity is basically a protective measure.

Unfortunately, the continued hunting of gorillas in Africa for food and trophies has reduced their numbers, threatening their survival. Conservation measures to protect gorillas in wildlife parks have been established in Africa.

The capture of gorillas in the wild for placement in zoos around the world is a practice of the 20th century. In early 2005, there were no mountain gorillas in captivity. Only western lowland gorillas were in captivity.

Zoos around the world have agreed to no longer accept gorillas from the wild. Instead, they now breed gorillas and then distribute them to other zoos. These breeding programs are like genetic "backups." To have a genetically healthy gorilla population in captivity, detailed genealogies are kept of gorillas bred from a "founder" of the line. The founder has usually been born in the wild.

Having gorillas in captivity has created a dilemma. Zoos are not the natural place for gorillas. They thrive best in the wilds, where they roam in groups. Study of the animals in captivity has shown that gorillas need companionship and are healthiest when in groups. This has led to the conclusion that single gorillas in captivity decades ago probably often died of loneliness.

Today, gorillas are placed in ecologically friendly habitats rather than being warehoused in cages. Researchers have developed large, open areas similar to gorillas' native habitat for them to roam. There, they can live together as a gorilla group and have the best opportunities to flourish. Research on gorillas in captivity seeks to know their individual behaviors, group dynamics, diet, breeding habits, parenting, and diseases.

— Andrew J. Waskey

GORILLAS, SAVING

Saving gorillas poses a great challenge to conservationists. Currently, gorilla populations suffer from habitat loss, hunting, and disease. The four subspecies of the large, black-haired great apes are found in Uganda, Rwanda, Zaire, Congo, Cameroon, and Nigeria. There are approximately 94,000 western lowland gorillas (*Gorilla gorilla gorilla*), 17,000 eastern lowland or Grauer's gorillas (*G. g. graueri*), 700 mountain gorillas (*G. g. beringei*), and 200 Cross River gorillas (*G. g. diehli*) left.

Gorillas belong to the same family as humans, Hominidae. They have the most herbaceous diet and are one of the most terrestrial primates. They locomote using quadrupedal knuckle-walking. Gorillas typically live in harem groups, consisting of one male, multiple females, and offspring.

Most of the early information on gorilla behavior was compiled by George Schaller and Dian Fossey, the famous aggressive mountain gorilla conservationist, and their associates. Fossey founded Karasoke Research Station at Parc National des Volcans (PNV) in Rwanda in 1967. Gorilla ecotourism was founded at PNV in 1978. Today, tourists pay between \$250.00 and \$400.00 (U.S.) for a permit to see the mountain gorillas for a few hours. Even with strict guidelines, such as most ecotourism agencies allowing only one visit of no more than six to eight people per day per gorilla group, the annual revenue earned directly from gorilla tourism has been estimated at \$3 million. When this figure is combined with the additional income received by funds earned indirectly (by hotels, restaurants, etc.), the total revenue may exceed \$20 million. This money is shared between Rwanda, Uganda, and the Democratic Republic of Congo (formerly Zaire). Such programs have aided mountain gorilla conservation by preventing farmers, poachers, trophy hunters, and loggers from endangering the gorillas and their habitat.

However, wars, conflict, and civil unrest beginning in the 1990s caused many gorilla ecotourism programs to close intermittently. Wars also drive many refugees into the mountain gorillas' previously undisturbed habitat, resulting in gorillas being hunted for food. Research on gorillas indicates that hunting pressure generally has a greater effect on gorilla populations than habitat disturbance. In 1996, the World Society for the Protection of Animals (WSPA) and the Cameroon Ministry of Environment and Forests (MINEF) held a conference

in Cameroon and addressed such issues. Although the official title of the conference was “The Impact of Forest Exploitation on Wildlife,” it is commonly referred to as “The Bushmeat Conference.” The attendees concluded that the bushmeat crisis is directly linked to the timber industry and is having a devastating affect on many animal populations, including gorillas. Gorilla meat is considered a delicacy in wild game markets. Logging brings humans and gorillas into closer contact. It is responsible for the demise of gorilla populations due not only to habitat loss and hunting but also to transmission of diseases such as cholera.

Western lowland gorillas and Eastern lowland gorillas are endangered, while mountain gorillas and Cross River gorillas are critically endangered. It is hoped that as research and conservation efforts continue, awareness of the plight of gorillas will increase so that our largest living relatives can be saved.

GOSSE, PHILIP (1810–1888)

In Victorian England, Philip Henry Gosse made an unusual attempt to reconcile the glaring discrepancy between the empirical facts of the earth sciences that supported the theory of evolution and the revealed

beliefs of traditional religion. As a fundamentalist creationist of the Plymouth Brethren sect, he held to a strict and literal interpretation of the story of Genesis; this Mosaic cosmogony required rigidly accepting both the sudden creation of Adam and the Noachian Deluge. Yet, as an avid naturalist, Gosse was unable to ignore that growing and compelling but contrary evidence in historical geology and comparative paleontology that supported the rational claims of the early evolutionists in the 19th century. His own scientific interests included ornithology and marine zoology. This well-traveled author and illustrator wrote nearly 50 volumes and even invented the aquarium. Yet he rejected outright the evolutionary framework.

Gosse hoped to resolve the contradiction between evolutionist science and fundamentalist religion by offering his own unique account of the planet, which would seemingly, at least for him, do justice to both conflicting conceptual worldviews. He presented a ridiculous explanation of terrestrial creation in two books, *Life* (1857) and *Omphalos: An Attempt to Untie the Geological Knot* (1857), both appearing in print just 2 years before the publication of Charles Darwin's *On the Origin of Species* (1859).

Gosse's argument clearly gave preference to biblical authority and direct experience rather than to empirical facts and rational inquiry. It is grounded in a crucial distinction between two modes of existence: preternatural, prochronic, or ideal time in the infinite and perfect mind of the personal deity before the act of divine creation and natural, diachronic, or real time of actual objects and events and relationships in our material world of change and development. Furthermore, the course of everything in both inorganic and organic nature is claimed to be a circle.

In his attempt to reconcile the biblical cosmogony with scientific evolutionism, Gosse firmly argued that the geological column with its sequence of rock strata and record of fossil patterns was divinely created all at once, along with the earth's existing flora and fauna types (including the human animal.) Therefore, at a single point, our planet suddenly came into being as an ongoing world containing a developmental series of fossils in rock layers that only suggest both an extensive physical past and a creative biological evolution before the earth's actual origin in the real space and diachronic time of nature itself. In this metaphysical scheme, the distinction between appearance and reality is crucial.

In short, our planet is at the same time as old as demonstrated by science and as young as claimed in the sacred scriptures. How is this possible? It is, if one assumes with Gosse that God created the earth with a built-in past: The stratigraphic sequences of rocks were suddenly formed at the instant of creation along with all plant and animal fossils in their respective places. This appearance of evolution accepts the results of the process while rejecting the real process itself.

As such, according to Gosse, the appearance of all geopaleontological evidence merely implies the pre-existence of rocks and fossils prior to the abrupt moment of a special creation through the omnipotent fiat of a divine creator only about 6,000 years ago. The formation of the earth occurred at a distinct point in prehistoric time, and the origin of life on the planet, along with our own species, was a violent eruption of organisms into the continuing circles of cosmic reality. The first forms of life suddenly appeared *as if* they had a historical past in the natural world.

Consequently, following this argument, all the geopaleontological evidence for a succession of countless epochs over millions of years, as well as for the progressive development of life on earth, is utterly deceptive, since preexistence is simply an illusion. The pristine world of divine creation had instantly intruded into diachronic time as if it had been partaking in an ordered continuity of early history spanning untold aeons. Briefly, this unorthodox interpretation allowed Gosse simultaneously to admit and dismiss all the accumulating geological, paleontological, and biological data for the enormous age of this planet and the vast inventory of inorganic structures and organic beings both upon it and within it.

Gosse rejected the eternity of inorganic and organic matter, as well as the mutability of species in the biosphere, since the flora and fauna of our earth are fixed and only a few thousand years old. In arguing his position, he even performed a thought experiment: although stressing that there was no human observation of antediluvian history, Gosse boldly imagined himself observing the first plants and animals of earth just after the moment of creation. In keeping within his view of things, these growing organisms would appear to have had a history, but in fact such an inference is fallacious, according to this interpretation.

As if this interpretation were not a sufficiently strange form of natural theology, Gosse even went so far as to propose that all the fossils of so-called early

life found in the alleged ancient rocks of our earth were placed in these geological strata by a personal God in a plausible paleontological sequence so as to deliberately test the faith of their discoverers, or perhaps even cunningly deceive the faithful. For example, he argued that Adam and Eve had been created with a navel by this same clever deity in order to simulate natural births from biological parents.

For Gosse, evolutionists are simply studying the divinely imprinted appearance of a seemingly ancient globe, because he claimed that there had been no gradual change of the earth's surface over the supposed vast aeons of planetary time and no slow evolution of plant and animal species throughout the equally assumed ages of organic history. Needless to say, this argument of *Life* and *Omphalos* was not taken seriously and had no major effect on the scientists, philosophers, theologians, or even the general public of the time.

Gosse was heartbroken and could not understand why his effort at reconciling evolutionary science with fundamentalist religion was rejected with equal force by both naturalists and religionists. Actually, since he believed that divine creation had taken place instantly, his own theistic cosmogony is not in step with the traditional 6-day story of Genesis.

Gosse's worldview is neither empirically convincing nor logically defensible. It is scientifically unrepeatable in principle, and it ignores the law of parsimony. There is simply no reason to appeal to an improbable possibility that today flies in the face of empirical evidence and common sense. A modified form of this position does surface now and then in the biblical fundamentalist and religious creationist literature of today. This whole scheme remains as the residue of a desperate attempt to synthesize the old beliefs of an outmoded theistic cosmogony with the advancing evolutionary sciences.

Gosse's belief in a sudden creation is grounded in an arbitrary point for the beginning of natural time. In fact, we could claim that everything still exists in the mind of God, waiting to burst into natural time. We may even ask, *Why was this universe created? Or Is this the only created universe?* There are numerous scientific, philosophical, and theological interpretations of this evolving universe. Gosse's metaphysical imagination rejected evolution in order to avoid a slippery slope from traditional spiritualism to pervasive naturalism.

GRAMSCI, ANTONIO (1891–1937)

Antonio Gramsci is considered one of the foremost Marxist theorists of the 20th century. Though he was not an anthropologist, his work has had a tremendous impact on the field of anthropology, and he was a major influence on social theorists of such stature as Louis Althusser, Raymond Williams, Pierre Bourdieu, Michel Foucault, Jürgen Habermas, E. P. Thompson, Eric Hobsbawm, and Stuart Hall. He reworked many of classical Marxism's key concepts (for example, ideology, class consciousness, base and superstructure) in ways that opened them up to engagement with anthropological analyses of society, and his concept of *hegemony* has been particularly key to critical explorations of the intersection of culture and politics. The field of "cultural studies" is rooted largely in interpretations and applications of his ideas.

Born in Sardinia and shaped by a difficult childhood, Gramsci was no armchair theorist, but an activist deeply engaged in political struggles, especially the factory council movement in Turin. As a young man, he abandoned a promising academic career to dedicate himself to journalism. His columns, articles, theater reviews, and translations of labor news from around Europe (especially Russia) were widely read, and he eventually became a leading figure in the Italian Socialist Party and, later, the Italian Communist Party. His political activity became increasingly confrontational after Mussolini's rise to power in 1922. He was a member of the Italian Parliament from 1924 until his arrest, along with other Communist Party deputies, in 1926. At his trial, prosecutor Michele Isgrò reportedly declared: "We must prevent this brain from functioning for 20 years." Despite suffering severe health problems in prison, Gramsci repeatedly refused to ask for

clemency from the fascist government. He was granted conditional freedom in late 1934 (though he continued under constant police surveillance), but he never regained his health and spent his last few years as an invalid, transferring from one hospital to another; these efforts proved futile, and he succumbed to a brain hemorrhage at the age of 46.

Gramsci's most influential writings were produced in prison. Eventually collected as the *Quaderni del Carcere*, or *Prison Notebooks*, they were published piecemeal after World War II, and attracted great attention and critical commentary not only in the West but also in the new nations emerging from European colonialism. Paradoxically, the limitations under which Gramsci produced his theoretical formulations are partly what made them such fertile ground for later scholars. In order to escape the vigilance of the prison censors, Gramsci wrote in a purposefully ambiguous style, avoiding explicit references to Marxism-Leninism. The theoretical framework that he sketched out was both concrete and open-ended, inasmuch as his formulations were usually framed within specific historical struggles or political questions, but pregnant with implications that extended beyond the particular case at hand. It is precisely this flexible, nondogmatic quality of his ideas that has allowed them to be engaged by numerous disciplines and applied to a wide range of social themes and contexts.

The *Notebooks'* content is wide-ranging, but it is Gramsci's concern for integrating political action with organized cultural activity that holds particular relevance for anthropology. Central to Gramsci's vision of political struggle is the notion of hegemony, which he conceived as a social order based on a combination of coercion and consent. Hegemony is totalizing in intent but never total in practice; since it accommodates and incorporates oppositional strains rather than repressing them by brute force, it must be constantly shored up and negotiated, and it often contains the ideological seeds of its own undoing. In order for the dominant sectors of society to construct a *hegemonic bloc*—a political consensus that incorporates a range of disparate social groups—the interests of the dominated must be articulated to the dominant interest. Since ideology plays a key role in this articulation, it can no longer be viewed as a merely superstructural phenomenon, derivative of economic relationships; rather, it is one of many elements shaping the evolution of political processes. This rejection

of a rigid division between an exclusively determining economic “base” and a determined “superstructure,” in favor of a more dialectic relationship between levels of social activity, distinguishes Gramsci’s thought from that of more orthodox Marxists, whom he criticized for their economism and reductionism.

It is this same idea that makes the concept of hegemony so attractive for anthropologists. Whereas classical Marxism relegated symbolic activity to the realm of superstructure (recall Marx’s example from the *Grundrisse*, which assigned the labor of the piano maker to the base and that of the pianist to the superstructure), Gramsci recognized that cultural activities, values, and loyalties are also active elements in the maintenance and reproduction of a social order. From this perspective, many of the domains of human activity that have traditionally interested anthropologists—artistic expression, language, popular culture, religion, and ethnic and regional solidarities—take on a greater political significance.

The concept of hegemony also required a more nuanced theorization of ideology than was possible within classical Marxism. Political observers had long noted that people do not always act in accord with their apparent class interest, nor are their ideologies necessarily predictable from their class position. Whereas classical Marxism resorted to the notion of “false consciousness” to explain (or rather, explain away) the failures of the working class to assume their historical role, theorists in the Gramscian tradition view ideology as too complex and multifaceted to be characterized as mere mystification. Individuals are nexuses of multiple interests, not just class interests; hegemony consists of evoking certain interests and muting others, to the point where the dominant consensus assumes the mantle of “common sense.” The work of articulating the common sense of the masses to “the upper level of philosophy” is the stuff of politics, that is, the construction of a hegemonic bloc. Key to this task are the “organic intellectuals,” who express the interests of their class through their cultural work, while endeavoring to bring other social groups under the leadership of their ideological vision. This “war of position” tends to be protracted, engaging multiple institutions within civil society before attempting to take control of the state. Within Gramsci’s view of hegemony, neither ideological domination nor class unity can be assumed a priori; they must be *produced*. Thus, ideology becomes not simply a reflex of one’s position in the class structure, but crucial terrain on

which political struggles are waged and political outcomes (partly) determined.

Gramsci’s rejection of the notion of an automatically unified class consciousness and his recognition that the common conditions of existence shared by members of a class are crosscut by other interests and loyalties led many anthropologists to analyze the origins of those conflicting interests and the ways in which other dimensions of oppression and identity intersect with the class dimension. In this way, Gramsci’s thought became of crucial interest to anthropologists concerned with ideological constructions of race, gender, ethnicity, religion, and the social movements and cultural forms arising out of these different types of collective experience. Social classes exist not as coherent social groups but as abstract categories that are fragmented in any actual historical formation. Politics thus cannot be seen as reducible to class, and identity itself is reconceived as multiple, fragmented, and contradictory. Ironically, the thinker who perhaps did the most to bring Marxist thought into anthropology also laid the groundwork for the decentering of Marx’s most fundamental concept—economic class—from the stage of social reproduction.

—Aurolyn Luykx

The depositing of the dead in graves is only known from *Homo sapiens* and *Homo Neandertalensis*. Graves belong to the earliest and most important testimonies of human culture. But in many recent cultures, burials do not imply as a necessary accompaniment any kind

Source: FreeStockPhotos.com.

of grave. The act of burying associated with ritual practices is a universal element of human culture and documents a dimension of human thinking beyond their individual lifespan, an awareness of the afterlife and of the highest social behavior. It manifests the emotional attachment between the living and the dead. Its universality is a strong argument for existing burials in the last common ancestor of all recent human populations. As the dispersal of humans started from the Middle East about 70,000 years ago, it seems plausible that burial practices evolved before that event. This corresponds with the early graves in famous Qafzeh (today's Israel).

Several criteria must be fulfilled to accept a site as a grave. Graves are defined as the deposition of remains of one or several dead clearly indicating an intentional act independent of specific locations. Graves can be situated close to settlements in caves or *abri* or far from them in the open field. It should always be possible to assign the cranial and postcranial skeletal remains individually. The mortuary practice is identified by the posture of the corpse, its orientation, any kind of decoration (for example, ocher), or burial

objects. Stones or flagstones protect the dead against scavengers but also “prevent” them from returning to the living. Unfortunately, former excavations have very often not reported many of these criteria.

Body position is a significant part of the mortuary program in many recent cultures. Corpses are laid down in mainly two types of posture, stretched out mostly in supine position or in crouch, where the degree of flexion may be different. Various interpretations of the crouch exist: It may adopt a posture close to the natural one during sleep, it may be imposed by the surrounding conditions, or it may prevent the dead from returning. The latter assumption is partly based on corpses found in bonds.

The orientation of the body can follow pragmatic reasons such as the topography of the terrain. Although data on grave orientation are scarce, an east-west orientation is often found already in early burials (Qafzeh, La Ferrassie) following the course of the sun. But other sites containing most burials (Skhul, Shanidar) show no grave orientation.

Burial objects comprise adornment, for example, pierced animals' teeth or snail shells, and are supposed

to indicate a group membership and/or a hierarchical position. Other objects are animals' remains, for example, bone or antler tools, or stone tools. Burial objects serve as support or nourishment of the dead in the other world, have magical purposes, or are oblations for the powers that be. Whenever the graves are excavated close to previous settlements, burial objects may also be just simple leftovers. Half of the burials of the Middle Paleolithic contained grave goods, while the vast majority of the Early Upper Paleolithic seems to have already contained such goods.

There is an ongoing debate whether humans of the Middle Paleolithic have already buried their dead or whether this only begins after the “symbolic explosion” characterizing the Early Upper Paleolithic period. At the end of the 19th century graves were denied because the Paleolithic humans were considered to be too primitive, but recent views challenge the idea by arguing that all early graves can be explained in terms of natural processes. Accepting the idea of early graves does not necessarily mean to accept an early “Homo religiosus” but to accept that taking care of dead may be a cultural constituent.

The site of Qafzeh has revealed that the oldest known graves dated to 100,000–90,000 years. Altogether, remains of 21 individuals were discovered, babies, children, and adults. It is a burial site of *Homo sapiens*, which also contains a 13-year-old Neandertal. All skeletons were oriented along a common axis. Qafzeh also contained ocher, which is only found in a few graves in the Middle Paleolithic but common in Upper Paleolithic graves. From the Middle Paleolithic, around 20 graves are unambiguously known that contain *Homo sapiens* and *Homo Neandertalensis*. In the Early Upper Paleolithic, the overwhelming majority of graves are *Homo sapiens*. Lake Mungo in Australia includes an ocher burial and the first recorded cremation already at about 40,000 years ago.

Though the subject of Neandertal burial is a hotly debated topic, the archaeological evidence indicates that Neandertals indeed buried their dead. About two dozen unambiguous examples of Neandertal burial are known dating from after about 70,000 years ago. These burials are found in southern France, the northern Balkans, the Middle East (Israel and Syria), and possibly from Central Asia, including the possible burials of infants at Mezmaiskaya Cave in the Caucasus and at Teshik Tash Cave in Uzbekistan near the Afghan border. A famous example is “Moshe,” a skeleton missing his head and most of his lower

limbs. It was found in the Kebara Cave (today's Israel) dated to 60,000 years. The grave also contained stone tools, like the one at Qafzeh.

Intriguingly, the earliest burials were all of modern humans. This has led to speculations that the chronologically later burial of Neandertals may have been a cultural assimilation. Another important aspect is that burials were never the norm for “ordinary” people. From the scarcity of graves and from the principle of actualism taken from all later cultures, it seems convincing that graves are privileged burial sites. It is worth mentioning that only since less than 200 years a grave with the personal name is accessible for everyone in Europe.

GREENBERG, JOSEPH (1915–2001)

A distinguished anthropologist and linguist, Joseph Harold Greenberg was most well-known for his work in universals of language and comparative language studies. He was born in Brooklyn, New York, on May 28, 1915, and died from pancreatic cancer on May 7, 2001. He was gifted musically, taught himself Hebrew, and in high school studied Latin and German while learning Greek on his own. He taught himself Classical Arabic in college. He graduated from Columbia in 1936 and received his PhD from Northwestern in 1940. He then served in the Army Signal Intelligence Corps for 5 years, taught for a year at the University of Minnesota, and taught at Columbia from 1948 to 1962. In 1962, he went to Stanford as a full professor, served as chair of the anthropology department from 1971 to 1974, and served as chair of the Committee on African Studies from 1964 to 1981.

During the academic year 1958 to 1959, Joseph Greenberg, James J. Jenkins, and Charles E. Osgood drew up a memorandum on universals in language at the request of a staff member, Joseph B. Casagrande, of the Social Science Research Council. That memorandum provided a framework for studying universals of language and was the organizing document for the Conference of Language Universals held in New York, April 13 to 15, in 1961. Ten papers presented at this meeting were published in *Universals of Language*, in 1963, which Greenberg both contributed to and edited. Greenberg's contribution, titled "Some Universals of Grammar With Particular Reference to the Order of Meaningful Elements," discusses 45 universals of language grouped into the following categories: basic order, syntax, and morphology. One of the most important notions that came out of the Conference of Language Universals was the concept of implicational language universals. Such universals can be generalized as "If a language has Structure X, then it must also have Structure Y." For example, Greenberg writes, "If a language is exclusively suffixing, it is postpositional. If it is exclusively prefixing, it is prepositional." Studies in language typology—which is concerned with understanding the structure of language at all linguistic levels: phonology, morphology, syntax, semantics, and discourse—were profoundly influenced by the papers that came from the Conference of Language Universals.

In 1963, Greenberg published *Languages of Africa*, which provided a linguistic basis for grouping Africa's 1,200-plus languages into 4 language families: Afro-Asiatic, Khoisan, Niger-Kordofanian, and Nilo-Saharan. Greenberg used a method called "mass comparison" to determine language family groupings. This method has been criticized by some linguists. Despite the criticism, his classification of African languages is still widely accepted.

Greenberg also classified native languages of the Americas into three families: Eskimo-Aleut, Na-Dene, and Amerind. He published his findings in *Languages in the Americas*. Despite supporting evidence from genetic studies and archaeology, this classification of Native American languages continues to be debated by many scholars.

Greenberg's ultimate goal was to compare all the world's languages, which he believed were genetically related to each other.

GROOMING

Grooming is a common everyday activity of many members of the order Primates. Grooming consists of going through the fur, using either the hands or teeth, to remove debris. Some species of primates have specific adaptations for grooming. For example, in prosimians, the incisors and canines of the lower jaw jut out, forming a comblike structure. Other species, such as tarsiers (*Tarsius*), have a distinctive grooming claw on the second digit of the foot that aids in grooming.

Source: © Robert Jurmain.

There are two main types of grooming, auto-grooming and allogrooming. Auto- or self-grooming consists of an individual grooming itself, while allogrooming is an interactive process in which one or more primates groom each other. While autogrooming is mainly used for self-cleansing, allogrooming may not be and is of particular social importance. In addition to simply cleaning the recipient's fur, allogrooming is an important mechanism for strengthening social relationships as well as being a display of affection. Allogrooming is used to reinforce social bonds between mating males and females as well as same-sex friendships.

During the process of grooming, individuals sit close to one another and are in constant touch. As a result of this close contact, relationships are strengthened and tensions are reduced. Recently, allogrooming among primates has been compared to massages. In humans, massaging newborns helps make babies healthier and calmer. In primates, grooming is done from the moment of birth throughout adulthood. It can be used to calm emotions following aggressive outbursts, and primates become much calmer when they are groomed by their partners or relatives. Among some species, the amount of grooming received is directly correlated with social rank. Higher-ranking individuals receive more grooming than individuals of lower rank.

The social-cognitive skills obtained via allogrooming may allow primates to live together in a cohesive fashion. Allogrooming also probably contributes to survival in large groups. Primates learn at a young age to keep some group members at enough of a distance to prevent ecological and reproductive costs, while at the same time not drive them away altogether. Allogrooming is also a means of communication. In some species such as chimpanzees (*Pan troglodytes*), prolonged periods of allogrooming occur when an old friend rejoins the group. In addition, some go so far as to suggest that grooming in primates helped promote language development and may have given rise to the evolution of gossip.

Grooming serves as much more than just a means of cleansing the fur and obtaining tiny treats (such as lice). It is also used to strengthen bonds, communicate, reduce tensions, and as a display of affection. In other words, grooming is the social glue of primate groups.

GUARANÍ ÑANDÉVA INDIANS

The Guaraní Ñandéva are an Amerindian group located in the Gran Chaco. Though most currently reside in Paraguay, Bolivia and Argentina also have communities. They are considered one of Paraguay's 17 to 20 indigenous groups. The following ethnonyms have been applied to them: Ñanaigua, Tapieté, Tapii, and Yanaygua. The last Paraguayan indigenous census (2002) notes that there are 1,984 Guaraní Ñandéva, 957 females and 1,024 males, in 14 villages located in the Central and High Chaco. Most live in the Central Chaco, Department of Boquerón. The majority are classified as rural (98.1%). While they speak a dialect of Guaraní and are placed within the Tupí-Guaraní linguistic family, their native material culture and way of life resembles that of other non-Guaraní Chaco groups (for example, the Nivacle and Manjui). Use of the native language is still vigorous in most communities.

Little is known about the Guaraní Ñandéva's cultural history. It is unclear whether they were originally Guaraní or if the Guaraní, who undertook several migrations in search of the "land without evil," acculturated them. Some scholars hypothesize that they are descendants of the Chané, Chiriguano, or Mataco Indians (or a combination of these and possibly other groups). The archaeology and history of the Gran Chaco, the greater environmental zone that includes the Paraguayan Chaco, reveal that this large area was an ethnic melting pot during pre-Hispanic and colonial times. Contacts between Bolivian, Argentinean, Paraguayan, and Brazilian indigenous groups were common.

Until after the Chaco War between Bolivia and Paraguay (1932–1935), most Guaraní Ñandéva lived in the drier and largely uninhabited northern area of the Chaco. The Ayoreo, considered Paraguay's least-aculturated group today, also lived in that area and sometimes had skirmishes with the Guaraní Ñandéva. Other traditional neighbors were the Toba and Manjui, and today the Chiriguano figure prominently as neighbors. The Guaraní Ñandéva were semisedentary agriculturalists who did much hunting and gathering. Some also kept a few goats and cattle. Survival required extensive knowledge of the flora and fauna and, most important, of water resources (where water was and how to obtain it). For instance, they used water stored in the bromeliad *caraguatá* and the tuber *yvy'á* (*Jacaratia* sp.). They also harvested plants like the *sachasandía* (*Capparis salicifolia*), which, though toxic, could be rendered edible by baking. Such knowledge, however, is dwindling.

After the Chaco War, there was an expansion of cattle ranching in the region, and most Chaco tribes became sedentary. The Paraguayan military actually helped the Guaraní Ñandéva establish themselves in the frontier zone of Nueva Asunción, since they sought to reaffirm Paraguayan control of the Chaco. But the Guaraní Ñandéva migrated to other areas once official support ceased. In time, incursion by nonnatives into native areas made it difficult for the Indians to maintain their previous way of life. Another event that brought more outsiders to the region was the opening of the Trans-Chaco Highway. This highway brought poor Paraguayans and Brazilians to the area seeking employment with the Mennonites or others as available.

Today the Guaraní Ñandéva continue to have a mixed economy, but it is one that increasingly involves the use of cash. In terms of wage-earning jobs, it is mostly the young men who have access to such jobs. The Guaraní Ñandéva, as the last census revealed, suffer chronic underemployment and unemployment. In the 1980s, some Guaraní Ñandéva participated in a prodevelopment and self-determination project sponsored by the Indigenist Organization of Paraguay (AIP); however, that project led mainly to the relocation of several Guaraní Ñandéva groups that had lived in worker villages of the Mennonite colonies. Today, they receive some assistance from the Association of Indigenous and Mennonite Cooperation Services (ASIM), a Mennonite nongovernmental organization that works with indigenous peoples advancing health care, education, and economic programs (mostly agricultural).

The Mennonites have promoted indigenous colonies, entities that are divided into villages comprising several households. The Guaraní Ñandéva community of Canaan, in the colony of Laguna Negra, is the most populous village. It has an elementary school where both Guaraní and Spanish are taught, a bilingual basic health care provider, and a modest Christian church originally promoted by a Mennonite missionary who resided among the Ñandéva during the early stages of the founding of the settlement. Canaan's residents have kinfolk in other locations, such as the northernmost Guaraní Ñandéva villages of the High Chaco. When these relatives must seek medical help in Filadelfia or go there for some business or official transaction, they often stop in Canaan. Canaan can be reached from Filadelfia, the principal urban center in the Central Chaco, by a dirt road. Those who have great financial need will sometimes request financial assistance during Sunday church services. Much singing—accompanied by the playing of guitars and the beating of a drum made from animal hide—takes place during a religious service; males and females sing, and both display great receptiveness to music. Christianity has not eradicated the practice of shamanism. The Guaraní Ñandéva have some shamans and consult them when ill or in need of other services, for example, bringing rain.

Traditional houses were generally small and flimsy. They were made with several ingredients: mud, wood, and grasses. Current dwellings are made with a combination of materials, including wood, mud, bricks, and some cement. Though floor mattresses are now common, they formerly slept in hammocks the women made with *caraguatá* fiber or on mats of animal hide. They had few material possessions and wore scant clothing. Today, they wear Western-style clothing, which is often modified for rural living. Some keep a few goats, sheep, cattle, and chickens. The gardens, meager when compared with those of other South American lowlanders, generally contain various types of squashes, beans, corn, and watermelon. While men clear garden areas, women and older men generally are the ones most involved in the planting and harvesting of crops. Men hunt when feasible, but very rarely fish. Older male and female Guaraní Ñandéva will gather various wild products, such as hot pepper and cacti fruits.

GUTENBERG, JOHANNES (1397–1468)

Johannes Gensfleisch zum Gutenberg is generally credited with the simultaneous invention of movable metal typefaces as well as the concept of mass production through the use of a printing press. The invention of printing using a form of durable and movable type would eventually serve the needs of the masses. It was to be hailed as one of the most important and influential catalysts affecting the course of human interaction and history.

Sparse local history and records have been handed down that make much of the private history and life of Gutenberg unknown and hypothetical. But records do reveal that Gutenberg was born into a Europe prime for a cultural revolution. Gutenberg was born in Mainz, Germany, in 1397, when Europe had recently come out of the Middle Ages and the Renaissance was just beginning.

He was baptized at the church of Saint Christoph and lived in a large house that his father Friele had inherited from the family of Gensfleisch zur Laden zum Gutenberg. Historical records support he was born into a patrician family. His father was one of four accountants in the city of Mainz. His mother, Else Wirich, was the second wife of Friele and the daughter of a wealthy Mainz merchant. 1414 records indicate Johannes was probably the youngest child, as a Friele and Else are mentioned as an older brother and sister. Into this patrician atmosphere, the Gutenberg children would have had some schooling or private instruction and would have enjoyed the pride of a self-confident and well-respected family.

There is nothing to indicate that Gutenberg as a young man had any leanings toward the church, political life, or scholarly study, but later records

indicate he did have a talent for technology—especially a familiarity and skill with metal working and manufacture.

Records indicate his relatives belonged to a guild or fellowship of coiners that supplied metal for the minting of coins for the church. But because he and his brother could not pass the necessary ancestral test, he never assumed this career. After his father's death in 1417, he later left for the city of Strasberg, Germany, and took up residence. Records indicate he lived on an income from annuities, paid taxes to the city of Strasberg, but never became one of its citizens. City tax lists enter him as either semipatrician, semi-craftsman, or as one who serves under no other individual. The influence from his contact with metal working translated into his becoming an independent craftsman. He ran a respected workshop, from which he was able to augment his living expenses by teaching a variety of handicrafts.

Court records also indicate he was quite active in pursuing court matters regarding errant family annuities from the city of Mainz as well as a vexing case involving a breach of promise to marry a patrician girl. However, no clear records exist indicating he was ever married.

In 1439, court records provide information about his involvement in a business venture to supply cast metal objects. It is in these records a reference surfaces to a “secret art” involving “something to do with printing.” Unfortunately, no written records by Gutenberg himself have ever been produced, but historical records indirectly reveal his persistent involvement with perfecting this new process.

Gutenberg moved back to Mainz and set up his workshop, eventually borrowing large sums of money to finance his laborious venture. Not long after, between 1452 and 1455, he printed about 200 copies of his famous masterpiece, the hand-cast 42-line Gutenberg Bible. However, a judicial hearing regarding his loans and debts resulted in the ultimate loss of his business and its eventual takeover. He died in Mainz around February 3, 1468. The process of printing he perfected, however, was to spread and become a major influence on Europe by the end of the 15th century.

Gutenberg's process of producing printed material for the masses through the use of a printing press using movable type established itself in major urban centers in Europe within the first few decades of the 1500s. By the end of the 1500s, the reproduction of written materials had moved from the scriptoria (scribal desk) and

well-organized book trade guilds to that of the printer's craft shop. This resulted in fundamental changes to society. A mainly scribal society became a typographical one. Average copies of early printing editions ranged between 200 to 1,000 copies, compared with a single book that took a scribe nearly a month or, depending on its complexity, a year or more to complete.

Prior to printing, scholars had great difficulty in accessing uniform data, especially concerning chronologies, maps, tables, diagrams, and other reference guides common today. Library collections were subject to contradiction and corruption after subsequent editions were copied over the course of time. Print publishing slowly evolved within these confines and conventions of the day. Old scribal systems and technologies eventually petrified, giving way to the emergence of new occupational groups, including type founders, correctors, typographers, indexers, translators, copy editors, illustrators, print dealers as well as the expansion of new commercial centers and related industries such as paper making, ink production, and marketing. Cross-cultural exchanges within these groups stimulated new forms of enlightenment and intellectual ferment. By the end of the 15th century, the expertise of medievalists had given way to the beginnings of the modern era.

A commercial revolution resulted as other closely interrelated changes began to affect the entire fabric of man and society. Market demands shifted to meet the demand for books. The revolution of having knowledge, references, and reliable resources available had a direct bearing on the economic, historical, political, legal, technological, and educational developments of society. The correction of false and erroneous data, especially pertaining to a wide range of reference materials, medical and scientific data, and so on, was enormous. The ability to cross-reference and compare texts resulted in the formation and dissemination of new ideas and thinking. Religious ideologies, educational opportunities, exploration to new lands, major discoveries, and the Renaissance itself began to reflect the impact printing began to have on society.

In particular, this sharing and discussion of facts, concepts, perspectives, and discoveries related to scientific research in the 19th century resulted in the publication of major books in biology, physical anthropology, and archaeology as well as specific ethnographic studies in the social sciences. In academic books and professional journals, topics ranged from geology and paleontology to ethnology and

linguistics. The publication of such works paved the way for Charles Darwin's *On the Origin of Species* (1859), which both revolutionized the conception of humankind and life forms in natural history and inspired new areas of scientific research from primatology to psychology.

While there have been many waves of change that have had far-reaching effects on society, we can hardly imagine their impact without Johannes Gutenberg's invention of printing. Johannes Gutenberg's collaboration helped solve one of the most vexing problems of man's persistent compulsions—to communicate easily, cheaply, permanently, and quickly. Thanks to Gutenberg, the invention of movable type became one of the most far-reaching technological achievements in history, and our achievements today can trace their roots back to his genius.

The Western use of the term *gypsy* denotes an ethnic group believed to have migrated out from India approximately 1,200 years ago, spreading throughout Europe, the Americas, and other countries. Known by many names (*Tattare* in Sweden; *Tsiganes*, *Getan*, or *Manus*, in France; *Tchingheane* in Turkey; *Zingare* in Italy; *Zincali* in Spain; *Zigeuner* in Germany; *Cigany* in Hungary; *Tsygane* in Russia), this ethnic group often, but not always, identifies themselves as *Rom* (singular), *Roma* (plural), *Romni* (feminine singular), *Rom* (masculine singular), or *Romani* (adjective). The origin of the term *Rom* is believed to be a modification of the Sanskrit word *Dom*, a man of low caste who performs song and dance for a living.

Gypsies are what is termed a *diaspora population* (dispersed group living outside a homeland). Believed to have left India for reasons that are still unclear, it is speculated they were connected with military activity in India against the Turk, Afghani, and other military forces invaders leading to migration 1,200 years ago.

Current Gypsy population size is difficult to accurately establish due to absence of accurate census data, but estimates range from 8 to 10 million Gypsy people worldwide, who are residing in at least 40 different countries. During the past 1,200 years, this ethnic group has experienced a history of widespread mobility and marginality, while enduring momentous, continuous, and extreme prejudice, hostility, and violence against them by the people in the countries they moved into. The frequent moving within countries was motivated by either their choice or others' force and depended upon the social climate of the host country at the time. They were the ultimate strangers, feared and used as scapegoats for whatever problems local peoples were coping with at the time that needed a concrete explanation—hence, blame the strangers.

Adaptation and segregation are key factors to understanding the Gypsy way of life. They tend to live simultaneously in two different worlds: the exterior imposed non-Gypsy world and the internal constructed Gypsy world. The differences between the two lifestyles reinforce prevailing Gypsy practices; unique Gypsy language usage, social customs, religious practices, and political and economic institutions are all effectively used to mark the boundaries that divide them from others. Ethnic boundaries in the nature of Fredrik Barth's dichotomy of "we" versus "they" are established, reinforced through contrasts, and maintained to divide and separate. Unique identifying characteristics have been developed over time that reinforce the necessity for group separateness, and for the Gypsies these include the group-reinforcing tendencies of being biologically self-perpetuating, internally sharing specific cultural values, and using shared internal communication forms and other unique characteristics that function to enhance and maintain border divisions. These peoples then can identify themselves as being necessarily different from others, reinforcing the separation. It is useful to add Manning Nash's (1978) description of an ethnic group as being a "self-conscious group within a nation state" with "boundary marking values" that include defining cultural regulators of "kinship" (family, partners, friends),

"commensality" (food preferences and taboos) and "common cult" (religious practices), which form a strong barrier between a specific ethnic group and the larger society. The boundary-maintaining mechanisms then allow Gypsies a cohesive reinforced coexistence within the boundaries and also provides a means of distancing themselves from non-Gypsies (*Gaje*) through reflection, interpretation, and reinforcement of the absolute necessity of reinforcing the differences.

The Gypsy ethnic group is primarily an endogamous (in-marrying), kinship-bound group, with preferences for unique ingroup edible food selection, preparation, and consumption practices. They do not eat with others out of fear of pollution. Their religious practices center on standards required for maintaining the ethnic group solidarity, being regulated and reinforced by known rules of purity (*marime*) and pollution. Objects that come into contact with the upper body are not to come in contact with the lower body. Separate basins and soap are used to clean upper- and lower-body parts and materials that come into contact with each, thus building contact walls between Gypsies and non-Gypsies.

Two different systems of political control operate concurrently within Gypsy life. One is the non-Gypsy institution law, customs, and structure and the other is the traditional internal ethnic group political institutions, laws, customs, and structure. They are often at odds with one another, causing conflict between Gypsy and non-Gypsy. Internal Gypsy political institutions operate within what is known as the *Kumpania* (extended-family group within the same geographical location), which is controlled by the interpretation and application *Romania* (traditional Gypsy law). The laws are interpreted by *Rom baro* (internal leaders) and enforced by internal gossip systems. Varying states of purity (*marime*) and attempts to avoid polluting states regulate the rhythm of daily life. When internal mechanism processes fail to produce the necessary and desired political and legal result, leaders will occasionally turn to outside (*Gaje*) authority for reinforcement. An unruly person may be turned over to the police for theft.

Expulsion is the ultimate punishment for a group member's violation of the rules that regulate internal harmony and control. Expulsion can be either for a defined time period or, in extreme cases, permanently. Failure to comply with the outside (*Gaje*) political and legal structure can also have consequences for members. Non-Gypsy legal systems and

laws are frequently at odds with internal Gypsy regulatory laws, practices, and values. Claude Cahn, the editor of a cross-discipline series of articles on the *Rom*, explores issues of *Rom* human rights violations, equality issues, hate speech practices against them, educational system inadequacies for them, media stereotyping and misrepresentation, justice systems misinterpretations and failures, and racial issues in connection with Gypsies living in both Europe and the United States. Gypsy populations frequently have been the object of extreme prejudice, persecution, negative stereotyping, imprisonment, expulsion, and enslavement, the ultimate example being that of the Nazi death camps with the goal of total genocide.

In the United States, Gypsies frequently borrow one another's social security numbers and American names, believing both to be the property of their entire kin group. This switching of identities creates legal dilemmas between the Gypsies and the exterior legal system practices. This common sharing of social security numbers allows Gypsies to follow their tradition of maintaining anonymity when in contact with *Gaje* and works to reinforce separation from non-Gypsy society. Incarceration in prison can cause a Gypsy tremendous hardship because of strictly enforced Gypsy purity (*marime*) and pollution practices and violations of these rules in connection with proper Gypsy relationships with food, body, cleanliness, and ritual separation from non-Gypsies.

Economically, Gypsies generally support themselves with low-status occupations that are often on the margins of the larger-society economic endeavors, with time-honored occupational traditions of fortune-telling, auto repair, used-car sales, migrant agricultural workers, peddlers, entertainers, hawkers, and metal workers. Explanation and interpretation of economic choices for minority groups are explored by Sway, using what is called the "middleman minority theory." The theory investigates how marginal or minority group occupation practices are selected, established, and maintained by those involved. Sway looks at how employment practices function to strengthen avoidance of full assimilation of minority groups into the larger social structure. He demonstrates how Gypsy *kumpania* and *vitsa* (extended-family groups with authority under a specific chief) divide up specific geographical locations among groups and members of groups. They then can control the overlapping of Gypsy economic opportunity, while allowing adaptation to a hostile host environment.

This control also provides for necessary occupational roles to be fulfilled that are not desired or undertaken by the elite and middle classes of a society. The Gypsies, in other words, fill a vacuum in the existing work market.

Frequently, the status of being either nonliterate or marginally literate further reduces occupational opportunities, while concurrently enforcing intergroup cohesiveness and dependency. The traditional language of the Gypsy, *Romani* is a verbal not a written language. This increases the necessity for face-to-face communication and group dependency. Reinforcing this practice is the preference for internal enculturation of the children, rejecting extensive inclusion in formal government or religious educational institutions. This is not to imply that Gypsy children do not attend schools. They do attend when convenient, and particularly when receipt of government financial assistance is predicated on children's school attendance. Questions need to be asked regarding length of stay, attendance, and level of achievement for the children. The Gypsies are known to prefer internal nonformal systems of education for their children, thereby reinforcing Gypsy values, practices, and beliefs. There are, of course, also Gypsies that are well educated and work within the economic structures of mainstream society.

Kinship structures are designed to enforce ingroup cohesiveness, with the extended family holding a position of primary importance. The Kalderas, or Coppersmith, of New York can be used as an example of kinship practices. The Kalderas migrated from several countries, primarily Russia, Serbia, and Greece. They share the *Romani* dialect and have almost identical cultural institutional values, beliefs, and practices. Membership is within a federation of patrilineal bands (*vitsa*) with heads of extended families serving on governing councils. Internal arranged marriage is preferred and occurs between *vitsa* groups. First cousin marriage is strongly frowned upon, further reinforcing cross-group, appropriate selection and creating linkages between groups. Typically, the elders arrange marriages, with residence after marriage and until the arrival of the first child with the groom's parents. This means that the couple is considered to be members of the groom's *vitsa*, becoming a recognized adults within the ethnic community attached to being married. Age grade status is established, with specific privileges and responsibilities attached to each maturation level in the life cycle.

as defined by the ethnic group. Both consanguine (by blood) and affinal (by marriage) relatives are vital in forming the networks of dependency and reciprocal support necessary for daily existence. *Vitsa* (kin group) solidarity is dependent on both group cohesiveness and on lineage tracing, occurring along both the male and the female lines. The status of all *vitsa* members is affected by the behavior of each and every individual member, reinforcing solidarity of the group.

Elaborate funeral practices reinforce continuation of the descent system over time, with beliefs in ghosts and spirits of ancestors of deceased relatives interacting with persons still alive. Material goods of the deceased relatives can cease being used, destroyed, sold, or otherwise disposed of. Williams recounts how a form of solidarity continues between the dead and the living by recounting how two members of the French “Manus” Gypsy group were in the midst of an argument when one of the men went into a nearby trailer and returned with a gun. Upon seeing the gun, the other man in the argument turned and walked away. This could be misinterpreted as the fear of being wounded that caused the man to walk away, but in fact it was the gun itself, having been previously owned by a dead family member, that provoked the leaving. The leaving was a sign of respect for the dead person and not fear of the other man’s using the gun. The actual physical disappearance of the body of the dead person is reinforced by removal, destruction, disuse, transference, or sale of the deceased’s earthly material goods, but the spirit existence of the deceased family endures across time and is kept alive in the survivor’s thoughts. Material objects that belonged to a dead person and that are retained represent the deceased person and must be shown.

Gypsies frequently adopt the dominant religion of the nation, state, or country where they reside. In part, this is an adaptive measure, an attempt to avoid past experiences of religious persecution inflicted on the Gypsies for not being one religion or another: “In Spain, Italy, France, they become Roman Catholic; in England usually Protestant; and in southeast Europe they are either Muslim or Greek Orthodox” (Gropper, 1975, p. 109). Within their own religious practices, they greatly fear the influence of supernatural ghosts, spirits, and souls of the dead that can influence their

lives. This can be seen as a departure from the dictates of traditional Christian religions that place much less emphasis on the dead influencing the living. Gypsies also have a belief in the “evil eye,” using various objects and rituals to deflect evil influences. In addition, the color red can be used to counteract the effects of the evil eye, along with a wide range of religious taboo practices and rituals aimed to influence unseen forces. Gypsies believe and also fear the ghosts of evil spirits that can make their children sick. In an attempt to “fool” the deviant ghost, they may rename a very sick child to divert attention. Gypsies also are known to believe in the magical use of numerology and the use of combination of herbs and charms to ward off evil spirits. This demonstrates how they maintain their own Gypsy religious beliefs and practices separately from those of the outside world.

Gypsy cultural practices are not static, and what is written here should be seen as ideal practices subject to individual person and group variation. Culture is a tapestry, with multiple threads that crisscross to create the design of ethnic group unification, choice, modification, adaptation, or separation, depending on the needs of the specific group, time, and place involved.

HADDON, A. C. (1855–1940)

Alfred Cort Haddon can take credit as the man most responsible for establishing and legitimating anthropology as an academic discipline in Britain. There were anthropologists before Haddon, but no one did as much as he did for the discipline in its early years. In Haddon's words, anthropology was the "Cinderella science."

Haddon was born on May 24, 1855, and was educated at Christ's College, Cambridge. From 1880 until 1901, he was Professor of Botany at the Dublin College of Science. In 1900, he moved back to England, where he lectured in ethnology at Cambridge and, after 1904, at London University as well. Haddon served as President of Royal Anthropological Institute and President of Ethnological Section of the British Association between 1902 and 1905.

Haddon's prominence as an anthropologist came as a result of the influential expeditions to the Torres Straits islands. The first tour, in 1888, was originally undertaken to study coral reefs of the islands, reflecting Haddon's original interest in zoology. The second tour, in 1898 to 1900, was specifically devoted to anthropological issues and included a team of people, several of whom were destined to make large contributions to the development of anthropology in Britain. The photographs and film from that tour remain very valuable to this day. Haddon wrote up his conclusions from the tours in articles in *Nature* and in the proceedings of the Royal Dublin Society. A large compendium of works covering all aspects of the Torres Straits expeditions was put together, which spanned six volumes. Haddon had the largest single role in the six-volume *Reports of the Cambridge Anthropological Expedition to Torres Strait* (Cambridge, 1901–1935), being involved

in some capacity in five of the six volumes. The first volume, on ethnography, was one of only two that came from a single author (the other being the second volume, on physiology and psychology, by W. H. R. Rivers). Less helpfully, Haddon's volume was not published until 1935, more than 27 years after Volume 5 had been completed.

Haddon was unusual in his ability to appreciate the power of relationships involved in his study of native peoples. He was more anxious than many of his colleagues to study native cultures in a climate of respect and with some attention given to helping them preserve their customs in the face of Western encroachments. Haddon appreciated the friendliness of the Torres Straits Islanders, particularly in view of their earlier sufferings "from the malpractices of white men." Haddon was strongly opposed to the often casual use of the word "nigger" by his colleagues.

He was also a consistent opponent to the fashionable theory of diffusionism, whose main champion was the Australian anthropologist Grafton Elliot Smith.

Haddon was brought up a Baptist but lost his faith, becoming an agnostic. He was a member of the Rationalist Press Association (RPA) and, after 1927, an honorary associate. He cooperated with the RPA on a couple of occasions. In 1910, his *History of Anthropology* was published as the fifth title in the *History of Science* series, a pioneering series of popular science published by Watts & Co., the publishing arm of the RPA. A revised edition of that work was published in 1934, as Number 42 of the Watts & Co. *Influential Thinker's Library* series.

Haddon's last works reflect well his progressive opinions. For instance, he wrote a preface (as did Sir Arthur Keith) for Ettie Rout's *Stand Up and Slim Down* (1935), a health book for women with obesity and constipation problems. Ettie Rout was a very

controversial woman, having achieved notoriety during World War I for helping prevent sexually transmitted diseases among soldiers by encouraging the use of contraceptives. In the same year, Haddon collaborated with Sir Julian Huxley and A. M. Carr-Saunders in a publication called *We Europeans*, which was devoted to demolishing the racial theories of the Nazis, in particular the claims of so-called Aryans to being a race apart and superior to all others.

In 1883, Haddon married and had a son and two daughters. His wife died in 1937, and Haddon died on April 20, 1940. The faculty of archaeology and anthropology's library at Cambridge is named after him.

HAECKEL, ERNST (1834–1919)

In Germany, Ernst Heinrich Haeckel devoted his life to defending Darwin's theory of biological evolution. He was not reluctant to consider rigorously the philosophical ramifications and theological consequences of cosmic evolution in general and human evolution in particular. As a natural philosopher, he contributed to a sound scientific understanding of the nature of humankind and its proper place in the universe (despite the unavoidable limitations of his Victorian epoch).

In Haeckel's major philosophical work, *The Riddle of the Universe at the Close of the Nineteenth Century* (1900), he presented a naturalist interpretation of evolution within a cosmic perspective. The dogmatic dualism of Kant and Spencer was rejected, showing Haeckel's familiarity with the chemistry, biology, anthropology, psychology, and history of philosophy

during his time. He was particularly influenced by Spinoza, Goethe, and Darwin. A major zoologist and evolutionist, he is primarily remembered for his early defense of Darwinism in Germany and for establishing his "biogenetic law." Committed to the view that both science and speculation are necessary for a sound interpretation of the cosmos, he developed his own scientific cosmology. His monistic philosophy rejected the following three theistic dogmas: a personal God, the personal immortality of the human soul, and the freedom of the individual will. Also, he rejected the concept of empty space but supported strict determinism.

Haeckel's philosophy of nature relied upon experience and inference (rational speculation), both sources of knowledge being held indispensable. It rejected anthropism, that is, that powerful and worldwide cluster of erroneous opinions that opposes the human organism to the rest of nature and represents it to be the preordained end of an organic creation, an entity essentially distinct from it, a godlike being. As a result, he rejected (a) the anthropocentric dogma, which maintains that humankind is the preordained center and aim of all terrestrial life (Haeckel advocated a cosmic perspective), (b) the anthropomorphic dogma, which maintains that God, the creator, sustainer, and ruler of the world, has human attributes and that the human being is therefore godlike instead of the other way around (Haeckel rejected all forms of theism but was sympathetic to scientific pantheism), and (c) the anthropolatric dogma, which maintains an ontological dualism and the personal immortality of the human soul (Haeckel's own view was monistic and, as such, strictly naturalistic).

Briefly, the antropistic view of the world that sprang from these three dogmas is in irreconcilable opposition to Haeckel's monistic system. Indeed, it is rejected by his new cosmological perspective. Likewise, he held that his evolutionary monism was capable of resolving the following problems: (a) the nature of matter and force, (b) the origin of motion, (c) the origin of life, (d) the order in nature, (e) the origin of simple sensation and consciousness, (f) rational thought and speech, and (g) freedom of will. Consequently, he maintained that the great law of substance remained the only simple, comprehensive, mysterious, and enigmatic riddle of the universe. He espoused the view that this law is the fundamental cosmic fact of reality establishing the eternal persistence of matter and force (this was the law that guided

his monistic philosophy through the complexity of the universe to a solution of world problems).

What emerges as crucial in Haeckel's philosophy is his severe criticism of the fallacy of anthropism with its anthropocentric, anthropomorphic, and anthropolatric dogmas. Clearly, he denied the basic assumptions of theism, for he held that his monistic, pantheistic, and evolutionary cosmology would eliminate these errors. In place of these dogmas, he advocated the law of substance, with its naturalist implications supported by scientific knowledge. Humankind is seen as a product of biological development, and all of its faculties are totally within nature. To Haeckel, there is no need for transcendental or supernatural assumptions (the independent existence of the external natural world prior to the emergence of humankind and the limited constituting ability of human consciousness are both accepted as basic facts of physical reality).

Haeckel found empirical support for his evolutionary perspective in paleontology, comparative embryology, comparative anatomy and physiology, and comparative psychology. Comparative morphology demonstrated that our species is a vertebrate, tetrapod, mammal, primate, and hominoid. There was even biological proof for the asserted close affinity of our species with the great apes. In all important respects, the symboling human animal presents all the anatomical marks of a great ape, with reason being the only aspect that essentially distinguishes it from all its lower or earlier evolutionary relatives.

Paleontology supported an evolutionary interpretation of the great chain of being, or *scala naturae*, previously acknowledged by the nonevolutionists. There is a hierarchy in nature represented by successive chronological developments, for example, protozoa, protista, metazoan, invertebrates, fish, amphibians, reptiles, birds, and mammals, as well as developments in plants and insects. As such, the paleontological record supported the evolutionary unity of nature and documented Haeckel's monistic view.

Embryology or ontogeny demonstrates a common parentage of all organisms in general and of all primates in particular. Embryology implies that all existing primates share a common ancestry, our species and the great apes (orangutan, chimpanzee, and gorilla) being the latest products of primate evolution. Haeckel formulated his own biogenetic law to express the causative connection that exists between

ontogeny and phylogeny: "*Ontogenesis is a brief and rapid recapitulation of phylogenesis*, determined by the physiological functions of heredity (generation) and adaptation (maintenance). . . . In man, as in all other organisms, the embryonic development is an epitome of the historical development of the species." Haeckel's biogenetic law of recapitulation was regrettably exploited by extreme cultural evolutionists and condescending racists at the expense of technologico-economically little developed and non-literate societies arbitrarily described as primitive and backward peoples. Later, this law was misinterpreted even more cynically by racist politicians in unethical ways of which Haeckel certainly would have disapproved.

Physiology and psychology demonstrated that the vital processes in our species are subject to the same physical and chemical laws as those of all other animals. Likewise, its mental faculties or psychic life (including its rational faculty) are said to differ from those of the nearest related animals only in degree and not in kind, that is, quantitatively but not qualitatively. The human mind or soul (consciousness) evolves during the ontological development of the human individual and is dependent upon the common structure and normal functioning of the psychic organ, the human brain. As a result of this naturalist interpretation of the development of mental activity, personality can lay no claim to immortality.

Haeckel acknowledged that reason does distinguish our species from the other animals, but reason is not a supernatural aspect of the human mind. He held that reason is an activity of the human mind that has evolved along with the evolution of the brain. To account for the evolutionary emergence of consciousness (and eventually the emergence of reason), Haeckel adopted a position of panpsychism. His position of panpsychism resulted from the investigation of comparative psychology. However, a distinction should be made between a moderate and an extreme form of panpsychism. A moderate form of panpsychism merely maintains that all living objects manifest an aspect (and therefore a degree) of psychic development or sensitivity (this is Haeckel's own position). However, an extreme form of panpsychism advocates that ultimately everything in reality is psychic in nature, and therefore an ontological monism grounded in mind is necessary. A naturalist may support an ontological monism grounded in naturalism, for the degrees of sensitivity manifested

Source: © Hulton-Deutsch Collection/CORBIS.

by biological organisms depend upon the development of the central nervous system and brain. As a result, one may speak of the naturalistic emergence of psychic activity. By maintaining that the human mind differs from the psychic activity of lower animals merely in degree, rather than in kind, Haeckel's view agreed with those of Huxley and Darwin. His position does not imply anthropocentrism, a doctrine that he rejected. He merely acknowledged that in the long series of biological organisms that have evolved, our species is the most complex, and that degrees of sensitivity in the function of mental activity are directly related to the degrees of complexity in the structure of the central nervous system and brain. Therefore, since its central nervous system and brain are the most complex in the animal kingdom, it is not surprising that the human animal should manifest the highest degree of consciousness. In fact, our species is capable of self-consciousness primarily because of its superior central nervous system and brain and their role in sociocultural interaction.

Haeckel accepted Huxley's *pithecometra* thesis, that is, that the differences between our species and the great apes are not so great as those between the apes and the lower monkeys. Denying the different proofs that have been given for the immortality of the human soul (i.e., theological, cosmological, ontological, teleological, moral, and ethnological), he thought that there are sound scientific arguments to support this denial (i.e., physiological, historical, experimental, pathological, ontological, and phylogenetic arguments grounded in empirical evidence).

While acknowledging the incompleteness of the fossil record in rock strata, Haeckel maintained that, in the course of human evolution, an ape-man without speech, or the "missing link" (*Pithecanthropus alalus*), had once existed between the prehistoric apes and the present human animal. Unlike Darwin, who correctly held that Africa was the birthplace of our species, Haeckel taught that Asia was the cradle of hominid evolution. In fact, he even hypothesized that an Asian landmass, which he referred to as Lemuria (now vanished), had been the geographical location where our species had its origin from a hominoid ancestor. Haeckel's own lectures on the evolution of our species were very popular. His hypothesis that the missing link would be found in Asia even inspired Eugene Dubois to travel to Java, where he subsequently discovered the fossil hominid *Pithecanthropus erectus* (1890–1892). Haeckel's hypothesis had actually led to a major scientific discovery in emerging physical anthropology.

Haeckel's monism rested upon the law of substance, which in turn rested upon two great cosmic theorems: (1) the conservation of matter (Lavoisier's chemical law of the persistence or indestructibility of matter presented in 1789) and (2) the conservation of energy (Mayer's and Helmholtz's physical law of the persistence of force presented in 1842). On the basis of all of this, Haeckel concluded that the sum total of force or energy in the universe remains constant, no matter what changes take place around us. Energy is eternal and infinite, like the matter on which it is inseparably dependent. The two cosmic laws are fundamentally one, their unity being expressed in the formula of the law of the persistence of matter and force. Haeckel referred to this fundamental cosmic law as the supreme law of substance (axiom of constancy of the universe). The law supported universal causality and cosmic unity. Haeckel's monistic ontology has benefited in the wake of Einstein's theory of

relativity. The demonstrated interchangeability of matter and energy scientifically justifies a naturalist monism, for matter and energy are merely two manifestations of the one ontological stuff of this universe.

There are six essential characteristics of Haeckel's view of the cosmos: (1) the universe is infinite in space, (2) the universe is eternal in time, (3) the universe is a *perpetuum mobile* (movement is an innate property of substance), (4) there is no internal purpose whatever in the universe), (5) there is an eternal repetition in infinite time of the periodic metamorphosis of the cosmos, and (6) the idea of God is identical with that of nature or substance. Haeckel's scientific and pantheistic interpretation of reality is reminiscent of the positions held by Bruno, Spinoza, Goethe, Humboldt, and Einstein.

Haeckel argued that evolution and theism are irreconcilable. The evolutionary perspective led to the paradoxical conception of God as a "gaseous vertebrate" or gaseous being (by the expression "gaseous vertebrate," Haeckel is referring to the invisible and personal aspects of the traditional Christian conception of God). He concluded that monistic pantheism is necessarily the world-system of the modern scientist and that the modern thinker who has science and art needs neither a special church nor a narrowly enclosed portion of space.

Haeckel thought it very probable that unicellular evolution had taken place on planets elsewhere in this universe and that higher plants and animals have evolved on these planets; very questionable that these higher plants and animals are identical in development to those on earth; wholly uncertain whether there are vertebrates, mammals, and humans on other planets; much more probable that there are different plants and animals elsewhere, and perhaps higher beings transcending the intelligence of earthy human beings. He was also confident that future progress in astronomy, geology, physics, chemistry, biology, and anthropology would bear out his positions.

Haeckel's cosmological and evolutionary perspective is expressed in the following fundamental theorems: (a) the universe is eternal and infinite, (b) its substance, with its two attributes (matter and energy), fills infinite space and is in eternal motion, (c) this motion runs on through infinite time as an unbroken development, with a periodic change from life to death (from evolution to devolution), (d) the innumerable bodies that are scattered about the space-filling ether all obey the same law of substance

(while the rotating masses slowly move toward their destruction and dissolution in one part of space, others are springing into new life and development in other quarters of the universe), (e) our sun is one of these countless perishable bodies, and our earth is one of the countless transitory planets that encircle them, (f) our earth had gone through a long process of cooling before water, in liquid form (the first condition for organic life), could settle on it, (g) the ensuing biogenetic process, the slow development and transformation of countless organic forms, must have taken millions of years, (h) among the different kinds of animals that arose in the later stages of the biogenetic process on earth, the vertebrates have far outstripped all other competitors in the evolutionary process, (i) the most important branch of the vertebrates, the mammals, were developed later (during the Triassic period) from the lower reptilian, (j) the most perfect and most highly developed branch of the class mammalian is the order of primates, which first put in an appearance (by development from the lowest prochoriata) at the beginning of the Tertiary period, (k) the youngest and most perfect twig of the branch of primates is our species, which sprang from a series of humanlike apes toward the end of the Tertiary period, and (l) consequently, the so-called history of the world (i.e., the brief period of a few thousand years that measures the duration of civilization) is an evanescently short episode in the long course of organic evolution, just as this episode, in turn, is merely a small portion of the history of our planetary system.

As our earth is a mere speck in the infinite universe, so humankind is but a tiny grain of protoplasm in the perishable framework of organic nature. Haeckel proposed that it is very probable that on many planets of other solar systems, plants and animals have evolved similar to those on earth, perhaps even higher plants, animals, and vertebrate-like beings with intelligence that may even far transcend our own species on earth. As such, he had envisioned the new science of exobiology with its logical consequence for exoevolution.

In *Monism as Connecting Religion and Science* (1892), Haeckel's science-oriented evolutionary philosophy had rejected outright homotheism (theoanthropomorphism), that is, attributing human shape, flesh, and blood to the gods. He held that the Christian concept of a personal God is totally erroneous in light of scientific evidence and the evolutionary

perspective. Unlike Darwin, Spencer, and Huxley, Haeckel was not reticent in expounding the naturalist and atheist implications of the theory of evolution as he understood them. His philosophy of humankind was grounded in the special sciences informed by critical reason. He held that the evolution of our species could be sufficiently accounted for by the sciences, that is, there is no need to distort or ignore established natural facts by dogmatically holding to unverifiable philosophical assumptions for the sake of retaining a theological orientation. He was bold enough to clearly point out that there are no longer any legitimate reasons for believing in a supernatural origin and spiritual essence of humankind. Hence, for Haeckel, there is no need to construct elaborate philosophical systems in an attempt to reconcile the special sciences with theistic theology. Theology is simply being replaced by ethically inspired and morally responsible scientific understanding and philosophical appreciation. His strong reaction to the dogmatism of the churches was reinforced by their refusal to acknowledge the implications of a naturalist interpretation of biological evolution. Few natural philosophers have been so honest and persistent in their quest for truth as Ernst Haeckel, who, even when considered solely within the limits of his time, remains a major scientific figure of undeniable historic significance.

Haeckel's *Last Words on Evolution: A Popular Retrospect and Summary* (1905) restated his philosophical position for the last time. The work contains three essays given at the last public delivery by the great man who was rightfully referred to as the "Darwin of Germany." He continued to maintain the thesis that naturalism, or evolutionary monism, and supernaturalism are diametrically and irreconcilably opposed. He wrote that the papacy is anything but a divine institution (describing it as "the greatest swindle the world has ever submitted to"). In his essay "Charles Darwin as an Anthropologist" (1909), Haeckel acknowledged his indebtedness to the great genius for the fact of organic evolution and its mechanism of natural selection, which support a monistic view of the origin and nature of humankind; but unfortunately, Haeckel resisted the new theories of mutation and the gene.

In his last book, *Eternity* (1916), Haeckel once again maintained the cosmic unity of matter and energy within the endless "becoming and passing away" of things in this universe, as well as the role of

chance throughout organic evolution. Of course, his respect for the special sciences, especially biology and anthropology, had not diminished. And he continued to stress the critical need for keeping church and state separated in the quest for truth.

Haeckel's works consistently discarded vitalism, teleology, positivism, agnosticism, and mysticism. They defended mechanism, hylozoism, a moderate form of panpsychism, pantheism, monism (matter-energy or matter-force), and the use of reason. Within his evolutionary framework, he never veered from his basic assumptions, that is, that naturalist or anti-spiritualist monism supports an eternal, infinite, self-sufficient, indestructible, uncreated, and endlessly evolving universe. Today, the empirical evidence to support the doctrine of evolution is sufficient to convince any open-minded scientist, philosopher, or even an enlightened theologian. In its general implications, Haeckel's *Weltanschauung* (worldview) remains untarnished after more than a century of continued scientific advancement. The fact that his millions of years have become billions of years is a correction resulting in a greater perspective that he would have happily embraced. It may be charged that Haeckel neglected to establish a rigorous epistemology, avoided mental analysis, underestimated the influence of social evolution (he could have added a supplementary set of cultural theorems, including a less ambiguous and more elaborate ethical stand), and even deified the universe. He was primarily a zoologist, and a great one, who, like Giordano Bruno and other pantheists, did not experience a need for a special divinity apart from and beyond that of the evolving cosmos itself.

Haeckel's views were the source of considerable controversy in biology, philosophy, and religion. He distinguished himself in zoology, making contributions to embryology and taxonomy. Unfortunately, he advocated a limited form of spontaneous generation to account for the origin of the simplest protoplasmic substance from inorganic carbonates. Nevertheless, he was convinced of the essential unity of the inorganic and organic worlds. In fact, he upheld the essential unity of the entire universe. His doctrine of substance (ontological monism) maintained that the ultimate nature of the stuff of the universe is unknown, but it rejected traditional dualism as well as atomistic materialism and idealistic monism. Yet, Haeckel's scientific writings advocated naturalism and rejected supernaturalism. His evolutionary

monism was grounded in the law of the conservation of matter and energy.

Haeckel advocated the reconciliation of science (empiricism) and philosophy (rationalism), but rejected religious faith as a substitute for critical inquiry. He held that introspection must be supplemented with experimental psychology and physiology. Clearly, for him, consciousness itself is a natural phenomenon and the product of biological evolution. Haeckel's pantheism advocates monism, a "natural equality" of egoism and altruism, the improvement of education and the human condition through more science, and is grounded in naturalism, humanism, and the evolutionary viewpoint within a cosmic perspective. With only a few but important modifications, this philosophical worldview remains in step with modern thought.

Ernst Haeckel died in Jena on August 9, 1919. He had spent an incredibly successful life as a professor and author, who belonged to over 90 learned societies and received many honors for his scientific research. An unabashed atheist, Haeckel had been courageous enough to take seriously the far-reaching consequences of evolution, while many of his contemporaries remained either indifferent or silent to the growing empirical evidence in the special sciences, from geopaleontology to comparative morphology, that documented the fact of evolution. Indeed, it is a fitting tribute to this daring evolutionary naturalist, with a cosmic perspective, that his book *The Riddle of the Universe* (1900) remains an important popular work of lasting intellectual value.

PRIMATE EMBRYOLOGY

Scientists hope that research on primate embryology will one day lead to finding a cure for many of the diseases humans now suffer from. Because primates are the humans' closest relatives in the animal kingdom, primate research is considered more useful than the use of rodents and other customary research animals. Humans share 95% of their genes with primates.

In October 2000, the Oregon Health Sciences University's team of scientists created the first genetically modified primate. The baby rhesus macaque was named ANDi, a reverse acronym of "inserted DNA." The little monkey was healthy and played normally with other baby monkeys. ANDi carries an extra gene that was inserted when he was an unfertilized egg. The gene is for a green fluorescent protein found in jellyfish and was inserted as an easily identified marker. This gene was used because it is known to be harmless and is easy to detect.

Scientists modified 224 eggs by injecting them with a genetically modified virus. The eggs were fertilized by injecting them with sperm. Forty embryos were produced. These embryos were implanted in 20 surrogate mothers. Five of the 20 adult monkeys became pregnant. Two infants were stillborn, and the other three were healthy males. ANDi is the only one proven by tests of his cells to show a successful integration of the transgene.

Scientists believe the process shows great potential for finding cures for human diseases. They contend that, for example, an Alzheimer's gene could be introduced into a monkey in order to study the effects of various Alzheimer's treatments. Researchers claim that the genetically altered mice and flies already being used in laboratories are poor models for human disease. Primates, being genetically closer to humans, should provide better models.

Many scientists hailed ANDi's birth as a great achievement. However, not all shared their enthusiasm. For example, members of the People for the Ethical Treatment of Animals (PETA) are alarmed. PETA is opposed to the use of animals in laboratories, and regard the animals as being

mistreated. PETA also doubts that genetically altered monkeys will prove useful in studying human disease. That remains to be seen. The procedure is difficult to accomplish with monkeys because of the complexity of harvesting monkey eggs and the scientists' inability to artificially control a monkey's reproductive cycle.

— Pat McCarthy

The word *Haida* is a derivative from the words *Ou Haadas*, meaning “inlet people,” the name replied when asked by the first Europeans what tribe or people they were. Their homeland is called Haida Gwaii and is situated along the archipelagos of the Queen Charlotte Islands of Canada and the southern extremities of Prince of Wales Island in Alaska. There are two main moieties (two equal subdivisions of the tribe) within the Haida people: Raven and Eagle. Under these are various sub-clans (e.g., Sculpin, Frog, and Double-Finned Killer Whale). The two moieties make up the political group within their society. One of the important rules in Haida antiquity was that people could not marry within their own clan; even if they came from another village, they were considered family, and so Raven clan members could marry only Eagle clan members and vice versa. Through the life of the Haida, the opposite clan plays an important role, especially through the potlatch, and at the death of a family member. It is at the potlatch that the opposite clan will witness the important events in the Haida life. It is the opposite clan that will attend to the funeral details during the time of grief. Whatever competitive potlatch may be happening, or feuds, there was always the knowledge of the interdependence upon the opposite clan.

The Haida were fierce warriors, feared by the surrounding tribes as well as those to the north and south. Accounts of their conquests were noted in the address of Dkh^wDuw'Absh Chief Seattle (*Si'ahl*), where he mentioned that of the few benefits he could find of the takeover of his homeland by Euro-Americans was that their presence and military would protect them from invasions of the Haidas and

Tsimshians. In the Haida society, however, it is not the conquests that make one great, as it is with the European cultures, but rather the person's ability to hold a potlatch. These ceremonial parties took place in the later part of the fall and winter months and required the host to be proficient in amassing and distributing wealth and property, which was proclaimed within their oratory tradition at these festive occasions. The wars were acts to procure the slaves and wealth of other tribes, which, in turn, were utilized in the potlatch preparation (for example, commissioning carvings and trading) and carrying out of the rituals within the potlatch.

The following factors led to the decline of the strength of the Haida people: the advent of European colonization of Canada and Alaska, which brought devastating diseases that spread and nearly decimated the Haida People, causing their forced relocation to the two main villages of Masset and Skidegate to escape the diseases; the ban of the potlatch in 1885, which lasted over 60 years; and the exodus to the new cities for work, which brought about the demise of the potlatching economy of the Haida people and their indigenous neighbors, making it difficult for them to live in the manner of their ancestors, and making way for the mercantilism of the industrial economy upon Haida Gwaii land.

Haida Life

The Haida, like their surrounding northwest neighbors, lived in a communal lifestyle, with several families sharing a “big house,” or more popularly known, a “long house.” Within their society were three statuses of people, the high caste, the commoners, and the slaves. The high-caste villagers were the families of chiefs; clothed in rich sea otter and martin pelt robes, they were the main citizens who gave potlatches. The commoners were the clan members who usually supported the chief in his potlatches, as well as their own, if they were able to acquire the material wealth to give one. The slaves were either born from slaves or were obtained through trade or war and made slaves; there were also debt slaves who worked for the person until his debt was paid. Within a village was a main “high chief” or “town chief,” and within each house was a chief or “house chief.” Usually, the successor of the chieftainship was acquired upon the death of a chief, and it was within a potlatch that the new chieftain became official. A chief could also hand

the responsibility over to the next in line (in a matriarchal society, it would be one of his brothers or nephews). Chief Albert Edward Edenshaw is an example of a well-known leader, who gave many potlatches during his life, initiated war expeditions, and carried on a slave trade. In later years, he changed direction toward Christianity, no longer wanted to participate in the rituals that were not approved by the church, and conferred his chieftainship on his nephew.

The training of children is important to cultures that survive with the knowledge of living in harmony with the natural and the supernatural. Leslie Drew Douglas Wilson was told during his research for *Argillite* (1980) that the “philosophical” knowledge was given from the *Naanas* (grandmothers) and *Chin-naas* (grandfathers) and that the uncles and aunts are given the role to teach the day-to-day lessons of survival and clan etiquette. There were strict rituals in training of the children as they approached puberty. As with other matriarchal societies among the Northwest tribes, when a boy was near the age of 10, he was sent to his maternal uncle to be instructed in fishing and hunting and the rights and property he would be inheriting from his uncle. The uncle would also train him in the ways of combat. For a girl, there were special provisions for her puberty training, which required isolating her from the rest of the community. During this time, upon entering this special location, she would be taught the etiquette of her people, as well as how to weave baskets and also to devote her time to learning other skills that would prepare her to become a matriarch of her clan and her people.

Food

With the wealth and bounty the ocean provided, the Haida were supplied with an abundance of salmon,

The original house posts from Old Kasaan, transported to New Kasaan. This was one of the last of the “Big Houses” to be lived in. Haida/Thlingit Pamela Rae Huteson is seated in the “Chief’s” area of the house.

halibut, red snapper, and other fish. They also had access to various sea mammals, seal, sea lion, and otters, for example. This abundance included many other types of sea creatures, such as crab, chitons, and scallops. They also gathered sea cucumbers, seaweed, and shoreline vegetation to supplement their diet. The various salmon runs that returned to spawn would arrive from July to November. The fish were hung to dry in the sun; they were also smoked on beams suspended over a low fire, within a smokehouse, as is done to this day. These were then stored in bentwood boxes to be used for feasting and sustenance during the winter months. They also hunted deer and bear and gathered seagull and murrelet eggs. Some of the plants gathered were wild rhubarb, various berries, fern, and Hudson Bay teas.

Artistic Expression in Daily Life

From their grand totems to the everyday utility objects of baskets, hats, bowls, and spoons, these were decorated with uniform and complex designs called “formlines,” as identified by Professor Bill Holms in *Northwest Coast Indian Art: An Analysis of Form*. The Haida and other Northwest tribal art was so prevalent

Whale totem at New Kasaan

Source: Photograph by Pamela Rae Huteson.

that Johan Adrian Jacobsen proclaimed them to be “nations of artists.”

With cedar in abundance and in close proximity of the Haida people, this provided the material for not only the memorial and “totem” poles but also houses and canoes. Fishing and hunting gear was fashioned out of the wood, roots, and withes into ropes, nets, bows, and arrows. There were bentwood boxes carved and steamed for storage and cooking. Mats were woven for eating, wearing, and sleeping. Woven and shredded bark skirts were also made. Among the indigenous tribes, the Haida have developed fine spruce root basketry, with designs woven in false embroidery. Sometimes formline designs were painted over the surfaces of their baskets and intricately twined spruce root hats by renowned artists, such as Charles Edenshaw. Each design woven or painted had a name, some of which are related to a specific clan lineage story.

The Haida artistic expression was also worn: tattoos; woven Chilkat robes; painted designs on skins that were crafted into tunics; Shaman’s aprons and leg coverings; hats and headdresses; and jewelry. Their jewelry had been made from bones, walrus tusks, and antlers, as well as shells of abalone and dentalium, argillite stone they called “black stone,” and copper. In the beginning, the argillite was used to create blades

and other utility items. Its high luster made a prized regal material. As the fur trade began to wane and the collecting of “native curios” expanded, argillite carvings became highly sought after. This craft quickly developed into a “fine art,” with artists like Charles Edenshaw and Tom Price among the early masters of argillite carving. The introduction of wool blankets and ready-made buttons to the tribes of the Northwest revolutionized clan expression of blankets worn by those of high caste. One maritime fur trader noticed jewelry fashioned from iron, and he instructed his men to begin

crafting jewelry out of their available iron and soon had to expand on his new trade item, as his Haida customers preferred unique jewelry. With the influx of silver and gold coins, these were fashioned into priceless bracelets, pendants, and earrings.

Belief System

As with the other surrounding Northwest tribes, the potlatch was not a religious ceremony. There was no systematic religion that was followed by rote; spirituality was reflected as more of a personal relationship with the universe as a whole, as they prayed to the “Power-of-the-Shining-Heavens.” It is not the humans that are superior, reveals Dr. W. F. Morrison JD, “There is nothing to be believed, everything just ‘is.’ Throughout our history are stories of animals, rocks, birds, fish, trees and other Beings carrying on conversations with human Beings.”

When death is near, it is believed that the family members who have passed on are near the person and upon death, the soul goes to a place of potlatch. The soul also has the choice to go back and be reborn within its family. This belief was brought into warfare tactics. When George Dixon, in 1787, had asked Chief Cumsheewa of the tribes on the mainland, he was told that they were the Haida enemies and that

the chief had not only “killed many of them” but also had their heads. Morrison explains that this action would prevent the soul from being able to find its way back and be reborn within its people. This would thereby eliminate these enemy warriors’ opportunities to return as potential warriors to fight the Haidas in future battles.

Death

When it was apparent that a death was near:

- There would always be some of the family singing the clan’s war chants, until the death occurred.
- An announcement that the time was near would usually be made by the family of the mate (widow).
- The opposite clan would see to the funeral procession, relieving the family during its sorrow.
- A shaman would prepare the person, painting the face and singing.
- The person was dressed in clean/new clothes for the spiritual journey.
- The family’s sacred ceremonial artifacts were placed all around the person.
- The grave box was placed near the person while he or she was still alive.
- After death, the body would be taken out of an opening in the wall of the house, not through the door.

Haida Trading and Influence

The currency within the bartering of the Northwest tribes consisted of some shells but for the most part of furs, especially the rich sea otter pelts. Trade items came from the surrounding neighbors, such as the Tsimshians for soapberries and eulachon oil in trade for furs. The regal Chilkat blankets were also secured from the Tsimshians. These were so costly only those of high caste could afford the price of furs for this prestigious item. The Haidas also traded with the Chinook, as they offered a rich assortment of goods from their trade with other tribes. The cedar in the Queen Charlotte’s was of a height and girth not found common in the forests of the Haida neighbors; this enabled the Haida to craft their coveted large canoes for trade items. Slaves were the labor behind the potlatch and daily life. It was not uncommon for each member of a high-caste family to have a slave to dress and prepare food for them. Their children especially would have a slave to watch over them and

make sure that they were safe; sometimes the child’s slave would be near the age of that child. Slaves were distributed as property during the potlatch. They could also be killed when a chief died, so that the slave would assist him in the spirit life. This dependence on slaves required much trading for them and acquisition through war expeditions.

The Haida were canoe voyagers. Their voyages provided the opportunity to observe many peoples and their traditions along the Pacific Coast, down as far as south as South America and Hawaii, and north to the Aleutians, for either trade or war. This is evident within their culture, through songs of other tribes (for example, Tsimshian and Chinook). The Haida language stands by itself and contains only “borrowed”

words, perhaps through trade. The Haida Gwaii land was in the early stages of cultivation when the Europeans arrived. One of the plants resembled the tobacco plant, which could have been obtained from the Californian tribes. Potato gardens were also found and thought to have been given by early explorers, yet there have been no journals to support that theory; Morrison tells how potatoes were acquired through the Haida's expeditions to Peru, as well as Hawaii. Oceanic travel was earlier refuted by Frederica de Laguna, yet it is noted that the Haida also have many traditions akin to the Pacific Islanders. Anne Cameron in *Daughters of Copper Woman* describes songs of the Nootka tribe in Canada, which start upon their journey and end when they land (e.g., in Japan or China). Alfred L. Kroeber noted the Northwest coast tribes have some characteristics that are similar to other oceanic indigenous people (for example, Māori and Hawaii), with their festivities employing wealth distributions and an elaborate and detailed carving style to represent their clan and heraldic lineage. The Haida and Tlingit culture have been influenced by the ancient Asian battle gear, seen in the close resemblance of their slate wooden armor to that of the Asian warriors. The Haida also share the Raven culture, which is found in other indigenous cultures, ranging from Siberia to Washington State.

Potlatch

Within the Northwest coastal societies, the Haida, Tlingit, Kwakiutl, and Tsimshian were very adept and had the ability to acquire large stores of food during the spring to fall months. These provisions enabled them to use the winter months in creativity and socializing, as well as allowing their carvers and weavers the luxury of tending to their craft to create clan and commissioned pieces, while the remaining clan members devoted their time to obtaining and storing food and creating daily utility objects. The potlatch was not just a feast or festival; it was the purpose of living. During the potlatch, the goals of wealth and status were realized for the clan through their participation in these important cultural events. The original intent of trade and war expeditions was to accumulate property in preparation for

their potlatches. If the parents were commoners, they may spend their life in the pursuit of raising the status of their children.

The word *potlatch* is a generic term from the Chinook trade jargon meaning “to give.” The Haida words for this occasion are:

- *Wāùgal*: When the property of land was distributed, the tattooing of crests and labrets were given to the children. Only the high-caste could have tattoos and be gifted at a potlatch. It was a time when adoptions were made and the highly coveted and honored names were bestowed. The families of chiefs carried the oldest and highest names; the Wāùgal was also a time that described a clan house-raising event.
- *Si ìk!*: This was a memorial potlatch given when a grave post (memorial totem) was raised. It is the opposite clan that takes the responsibility of attending to the funeral procession, and it is within the Si ìk! that the opposite clan is honored for the gratefulness of the services rendered during the time of sorrow.

It could take years to prepare and accumulate the wealth for a potlatch. These festivities were given for the children. In Haida culture, people could be high caste only if their parents had given potlatches. If their parents were commoners, they themselves

could not rise in status; they could only make a better future for their children. The more tattoos the person wore (i.e., on the arms, legs, back, or chest), the more visible was his or her status, as each series of tattoos displayed represented a particular potlatch, or potlatches, held by their parents.

In an oratorical society, it is crucial to have witnesses present when the wealth is displayed and to orally and visually record the prestige transferred via property (for example, of names, tattoos given, land, trade routes, crests, stories, and so on). Without the witnesses, there is no proof the action took place, and the credibility and evidence is lacking for the prestige claimed. The witnesses are then paid, first, by providing them lodging and meals during their stay and, second, with a wealth of gifts at the end of the festivities. Great care was given to the gifts/payments and to make sure that the gift matched the caste and position of the guest/witness. The guests were also gifted with food to see them through their journey home.

Along with the ancestral reenactments within the dances of the potlatch, there were also dances done by the shaman and high chief, as they trained their apprentices and “put the power” into those “inspired,” as told to John R. Swanton, and also that the spirits, such as the dog-eating spirit, “came through” the dancer. There were spirits that would come through both men and women and those, like the grizzly bear spirit, that came only through women. In Ullie Stelzer’s *Haida Potlatch*, some of the songs were sung with no dancing, as reported by a Haida Elder, due to either the “sadness” of the song or the “seriousness” and solemnity of the occasion. This was done by the singers at Klawock Alaska in 1994, when two teenage boys of both Tlingit and Haida ancestry were dealt within a traditional manner by the Tlingit banishment court. Since the boy’s were also of Haida descent, a Haida “judge” was appointed a commission to preside with the Tlingit “judges” to administer these unique alternative and traditional tribal justice proceedings, and was consulted throughout the duration of the banishment.

Acculturation

It is surmised that Spain was the first to encounter the Haida. The journal of Frays Juan Crespi and Thomas de La Penn, who accompanied Juan Perez, in 1774, and the Haida story of the first contact with Europeans contain many of the same elements. For example, there was a canoe that went out to meet the ship, wherein an elder stood within the canoe and danced, and the eagle down of peace was spread upon the water. The acculturation of the Haidas began with the

maritime European fur traders and explorers. Due to their extensive travels and witnessing other cultures to the north and south of them, these contacts were viewed as a positive enrichment of their culture, and as a result, Chief Edenshaw exchanged names with Captain Douglas upon the second contact.

Little was known of the customs and traditions of tribal people, in the early years of maritime trade. Although there were protocols of international law and fair dealing among the nations, the indigenous people were seldom apprised of these accords by the dominant society. Etiquette was still in its infancy

concerning the interactions with tribal people in the “new worlds.” The rash treatment of some Americans created a distrust of “Bostons” among the Haidas. One well-documented incident happened at the southern extremity of the Queen Charlotte Islands, at Houston Stewart Channel, in 1791. Chief Coya's people were not interested in weaponry or iron; they, however, observed the prestige associated with the new apparel that the maritime traders modeled. As a result, what clothes couldn't be bought through trade were taken while the newly washed clothes enticingly hung to dry on deck. For this “crime,” two chiefs, one being High Chief Coya, were assaulted by having their hair cut (only slaves had their hair cut), whipped (another slave treatment), and their legs forced into canon barrels, to name a few of the indignities forced upon these chiefs. Their people were not only made to return the articles, but their remaining furs, for which Kendrick claimed that he gave them a “fair” deal when he'd paid for the them. In these actions levied against Coya, he and his people were belittled, insulted, and unreasonably penalized, out of proportion to the nature of the purported criminal offense. An attempt to regain his position was made the following year with the attack on the *Lady Washington*, which not only went bad, but also inspired a shaming song called “Bold Northwestman” thereafter sung by the sailors. Coya was reduced to the lowest of the commoners.

During the time of colonization of Canada and Alaska, totems and other artifacts were collected for exhibits, world fairs, and museums of natural history. Haida Chief Saanaheit of Kaasan, on Prince of Wales Island, in Alaska, donated his house posts, Fog Woman pole, and canoe to collector John G. Brady, with the understanding that these treasures would be returned to Alaska to become “memorials” of his people. These memorials now stand in the Sitka National Historic Park in Alaska. When the exodus to major villages started happening in Alaska, there was a yearning by the Tlingit and Haida tribes alike to have totems there with their people. The Civilian

Conservation Corps (CCC) was created to make new jobs. In Southeast Alaska, this took the form of a joint partnership with the forest service, which employed village carvers to transport totems to make parks; the totems that could not be restored were recarved. This not only satisfied the Alaskan Tlingit and Haida tribes by having their totems in their new villages but also rekindled the art of carving.

Present-Day Haida

For a time, the only carving that was done was for tourists and collectors; the masks and hats that were made by the carvers in the mid-20th century tended to be for artistic pieces only, as some were too heavy for actual use. As the revival of potlatches spread, new totems began appearing on Haida soil as a new generation of apprenticing carvers began studying their craft. The Haida Elders were sought for their wisdom and knowledge of the nearly extinct Haida tradition, which prompted Elders like Robert Cogo and his wife Nora to document the Haida legends, foods, and language for future generations. Today, the Haida language in its various dialects is being taught to the youth and adults alike, as the interest in the Haida culture increases. Songs and dances were revived for the reintroduction of the ceremonies. In some communities, there were no examples of male dancing, and either a dancer from another village had to come to teach the new male dancers or they had to go out and learn the movements of the animals they were representing and put them into their dance, as Haida carver Robert Davidson experienced when preparing for his potlatch, which was recorded by Steltzer.

Today's Haida are a modern people, living in a high-tech world, wearing the latest fashions, and dealing with the negative effects upon our environment. Beginning with the prized Chilkat dancing robes, there is a long history of people willing to pay high prices for fashionable and prestigious works of art. There are a growing number of artisans who are applying the beauty and complexity of formline art to clothing. Leading this trend within the international

Haida Carver Sáádúúts-Robert Peele standing by his third dugout canoe, the second that he will be giving to a community, to reintroduce their cultural connections. Robert says, "We are here to take care of the earth. Somebody will have to be responsible for its [the canoe's] care."

realm is Dorothy Grant, from the Queen Charlotte Islands. Her designs are not only in the height of fashion but also contain price tags ranging in the thousands. It is not uncommon to see Grant's creations worn at potlatches and other prestigious occasions.

In the past, a costly war could mean lives lost on the battlefield of their fellow northwestern-coast neighbor's homeland. Today's wars with the Haidas are battled in the courtroom or in the media, as a small business called "HaidaBucks," originating in Masset, experienced. When Starbucks filed a lawsuit against them, it was assumed the small business would back down and change their name. Not only did the Haida business not back down, but they obtained powerful backup legal support and launched a campaign for their right to use the word *Bucks*. The HaidaBucks Web site contains the story of how the mighty Starbucks company backed down.

As populations have migrated and intermixed, animals have also accompanied them. Islands in the "new worlds" have felt negative impacts from the introduction of some animals, such as the rabbit hordes in Australia. The environment and maintaining a balance on their islands is of concern to the Haida people. The murrelet eggs from the Auk family of diving sea birds have been in the Haida diet from

time immemorial, and certain families owned the sought-after egg-gathering privileges of the islands and rookeries of the Queen Charlottes. However, due to the increased human activity of visitors from outside of the Queen Charlottes, Norway rats have invaded the satellite islands that have been the nesting grounds of the murrelet. This has caused a decrease in not only the numbers but also in the varieties of the nesting population, causing emergency measures to eradicate these predators.

The Haidas have become a very well-traveled people and have integrated many customs and technologies not only into their lives but into the lives of their neighbors as well, for example, the introduction of cultivation to the northwestern area. They have become a modern people, drawing stability from the roots of their culture, standing resolute, yet bending like the ancient cedar; and they are spreading their wings and soaring like the Eagle to great heights, into the new age and technology that surround them. The Raven culture, once denied them, is becoming reborn within the people and taking new dimensions and meanings. Truly, the Ancient Ones, the “Power-of-the-Shining-Heavens” are still watching over “Ou Haadas,” the “inlet people.”

Haiti is a country in the Caribbean that occupies one third of the island of Hispaniola. When Christopher Columbus set foot in Haiti in 1492, the island was inhabited by the Tainos Indians, who were put into slavery by the Spanish conquistadors. Within 30 years, the Indian population was decimated by the harshness of their new conditions and the diseases brought by the colonizers. To continue expanding their empire, the colonizers turned to West Africa as a new source of people to enslave. Struggle between colonial rivals to control the gold mines in Hispaniola ultimately led the Spanish to agree, in 1698, to a treaty granting the French control over the western part of the colony. Under French colonial rule, the western part, renamed Saint-Domingue, was transformed into a complex plantation system based on a sophisticated capitalist enslavement of Africans, who composed the majority of the population. The wealth of the colony attracted bitter struggles and wars between colonial challengers such as the British, the Dutch, and the Spanish, and after brief periods of conquest by each of these powers, the French again prevailed. During the 1700s, the century of philosophical enlightenment and revolution, Saint-Domingue was the richest colony of France, the major source of power and wealth that underwrote every sphere of French society. The contradictions inherent to the colonial and slavery systems in Saint-Domingue and the circulation of ideas of freedom and equality fostered by the Enlightenment (and culminating in 1789 in the French Revolution and the General Proclamation of the Rights of Man) generated the ultimate conditions for a general slave revolt. It started in 1791 and climaxed in the revolution that overthrew the plantation system and, after a 13-year war of independence, transformed the colony into a new country renamed *Haiti* (the original name of the island prior to colonization).

The epistemological status of Haiti and its social formation in the social sciences, specifically in history

and anthropology, is as problematic as Haiti's positioning in the latter disciplines. The Haitian revolution (1791–1803), against three centuries of slavery and colonialism, took place during the Enlightenment project; and this along with the emergence of Haiti in the modern world at the onset of the 19th century (1804) challenged the dominant paradigm of racial differences and hierarchies well ingrained in Western modern thoughts and narratives. For the philosophers of the Enlightenment, the precursors of modern history and anthropology, humans were internally differentiated on the basis of biology and culture, which provided the basis for a hierarchy of races and cultures, of which Westerns Europeans constituted the finest achievement of civilization. The revolution that transformed Saint-Domingue into Haiti was at the time deemed an inconceivable embarrassment, for it did not fit the project of men as defined in Western thought, even though liberty and equality were the ideals pursued by the Western thinkers of the time and concretized by the revolutionaries in the Caribbean. Indeed, the emergence of a Black republic was an impossible contradiction. The dominant Western narratives conceptualized and characterized Haiti as a “state of exception” in that for Europeans and Americans in the 19th century, the very existence of a former slave/Black-African-run republic tapped deeply into the contradictions that lay behind the Rights of Man proclamation, namely, a universalism on one hand and an evolutionism on the other. And from this latter perspective, it was necessary to discredit Haiti in order for Euro-Americans to enunciate their notion of civilization. This act, by its very nature, served to centralize the exception, which explains why Haiti figured so centrally in the entire narrative of the present. Haiti's exceptionalism was intrinsic to Euro-America's conception of itself, just as the power of Euro-America to normalize itself became intrinsic to the imagination of Haiti.

While all the great colonial powers and slave-holding societies conspired to contain the Haitian revolution at the margins of history, anthropological reports too were questioning the viability of a nation-state made of “black people,” plagued by cannibalism, cruelty, and immoral promiscuity. The Comte Arthur de Gobineau summed up the racial ideas that at the time dominated anthropology (scientific racism) to lay down the fundamental inferiority of the “black race” and its unfitness for progress and civilization

(the inequality of human races). Based on these ideas, Gustave d'Alaux reported in 1856 how Haiti due to the barbaric nature of its race was destined to failure. Alaux took on the new political system that was being built in the country to illustrate the despotic nature of Haitians and situate them in African tribal traditions. Others described an absolute incompatibility between the idea of a Haitian country and modernity itself. In his widely read book *Hayti or the Black Republic*, Sir Spencer St. John (1889) showcased Haiti to demonstrate that the “negroes in the great scheme of nature” continuously make apparent that they have no capacity “to hold an independent position.” “As long as he [the negro] is influenced by contact with the white man, as in the Southern of the United States, he gets on very well. But places [*sic*] him free from all such influence, as in Hayti, he shows no sign of improvement” (p. 134). According to St John, in absence of the “white master,” the Haitians are “falling into the state of the inhabitant of the Congo” in Africa. As William Cohen, among others, has shown in the context of the French colonies in Africa, images of Black people carved during the 18th century were critical in the development of discourses in anthropology, the science of “man,” which, at least through the 19th century, viewed *culture* as shaped by *biology*. In these discourses, Africa epitomized the “heart of darkness,” and Haiti was its expression. Since then, the historiography and anthropology of Haiti have been able only to define the country in negative terms when not systematically engaged in “silencing the past” when it comes to Haiti. The “horror of Saint-Domingue” during the time of the revolution, despotic political leaders after Haiti's independence, voodoo, cannibalism, black magic, poverty, human degradation, and failed nation-state narratives about Haiti in the social sciences have all cultivated a rhetorical depiction that Haiti is a reverse mirror of the West, the location of barbarism versus civilization.

These rhetorical depictions also provided the very frame within which Haiti would define itself in relation to the world and would rely upon throughout the 19th century to formulate its responses to anthropology. While Haiti was being conceptualized as a state of exception—the Black-run nation that proves that Blacks cannot run a nation—it was simultaneously being constructed in Haitian anthropology in terms of hybridization, imbrication, melding, and intersplicing of African and European values and practices. For instance, voodoo is at once an indice of

barbarism in terms of political ideology of the modern Euro-American but also the intersecting of Catholicism and African worship systems in ways that cannot be reduced to any simple combination of the two. The result is a notion of the indigenous that is, conceptually, the inverse of the state of exception, the transcending of the latter implicating the abolishment of the former, though this has always remained difficult to formulate, let alone practice, because the notion of the indigenous is one of the chief ideological weapons used to fend off intellectual imperialism.

On one hand, Haitian elites challenged Haiti's images in Western discourses by embracing a positivist anthropological perspective to locate their country and its people in a position that supplants the Africans closer, however, to the Europeans. Early Haitian anthropologists, while rejecting scientific racism and its thesis of racial inequality, embraced the barbarism-versus-civilization paradigm to situate Haitian society and its elites at the avant-garde of African backwardness. According to this view, even when the majority of the inhabitants of the new republic are practicing "barbaric" religious practices (for example, voodoo, or *vodoun*) and are judged, like the Africans, to have no clear concept of religion, the Haitian elites stand as an enlightened guide for the masses (and the "black race" in general), which with time will become civilized. Among many other writers, Louis Joseph Janvier published *Equality of Races* (1884), Antenor Firmin wrote *Of Equality of Human Races (Positivist Anthropology)* (1885), and Hannibal Price wrote *Of Rehabilitation of the Black Race by the Republic of Haiti* (1891) in response to the thesis of inequality of races and the inferiority of the "black race" that dominated 19th-century discourse in Europe and the United States, articulated in anthropological thoughts of Arthur de Gobineau's biologization of history and Herbert Spencer and other Western writers' Social Darwinism. In these publications, the writers tried to displace the focus of anthropology to its "true" object: how human races are evolving toward "the" civilization, epitomized by Western Europeans. To do so, these authors called attention to a new understanding of uncivilized cultures as a necessary step toward civilization but not as a biological mark that prevented people from these cultures becoming civilized. Haiti (through its elites), according to this model drawn essentially from Auguste Comte's sociological theory, showcased how African people would move away from barbarism.

The dilemma, of course, for the Haitian elites was how to anthropologically write on Haitian subjectivities as they simultaneously challenged the discursive depictions and constructed images of Haitians and Africans (Black people in general) without recourse to the very categories provided by 19th-century anthropology in the first place. How can a discipline such as anthropology, constitutive of colonialism that provided the categories that depict Haiti as the quintessence of difference and alterity be appropriated and used by Haitian elites to "scientifically rehabilitate the black race" in general and Haiti and the Haitian people specifically.

As the first Black Republic in the modern world, Haiti's singular dilemma consisted in whether to reject its African heritage and fully embark in the Western project in order to show the world that it is a "civilized" country or to embrace its African heritage and reconfigure it within the confines of the nation-state. This dilemma resulted in the development in Haiti of two different cultural worlds: (1) the Western (French)-oriented sociocultural project, embraced by the upper classes and instrumentalized through the control of the apparatus of the state and the official (public) institutions as well as the social valorization of the French language and Catholic religion, and (2) the African-oriented rural project, agriculturally based with its Creole language, vodoun religion, and West-African-inspired traditions and cosmology. These constituted a system of two autonomous cultural worlds within which discourses on identities as well as sociopolitical practices would develop. Curiously, while the depiction of Haiti's nonviability was reinforced by anthropological discourses on races, it was to anthropology that the Haitian elites turned to seek to formulate their responses to questions raised by Western writers. Even more curious is the fact that no significant segment of Haitian elites has ever fully embraced Africa or Europe. Yet in their responses, Haiti's rural classes, the vodoun religion, the Creole language, and the rural family configurations and traditions were relegated to mere folkloric practices—when not represented as barbaric, retarded, or pathologies to be cured by civilization. Paradoxically, this mode of writing about Haiti by Haitians themselves strengthened the negative depiction it intended to challenge; it constituted what Gustav Desai referred to, in the case of African intellectuals' production of colonial Africa, as "dangerous supplements" to the dominant rhetorical depictions of Haiti.

Haitian elites' dilemma about Haiti's African heritage is constitutive of the Haitian soul and therefore addresses the question of the extent to which narratives intended for Euro-American consumption must be internalized locally (for example, the Creole language as inherently inferior or vodoun as barbaric). Indeed, these narratives generated counternarratives embraced by other segments of the same elites, with a political background formulated around color lines opposition (Black versus mulattoes) in their struggle for hegemonic powers in Haiti. In other words, the Haitian anthropology is not a unified stand in relation to Haiti's dominant characterization abroad.

During the 20th century, anthropology in Haiti introduced a new realm of interpretations, due to a combination of circumstances both in Haiti and in the Americas. The struggle between factions of Haitian elites over political and economic control of Haiti throughout the 19th century only reinforced the marginalization of urban and rural masses and precipitated the collapse of Haiti's public institutions. At the beginning of the 20th century, Haiti's political instability was seized by the United States as an opportunity to gain control of the country. The United States' invasion of Haiti in 1915 led to the development of strong nationalist and indigenous movements. A segment of the Haitian elites, including Haitian anthropologists like Jean Price-Mars, inaugurated a different approach on Haiti and its sociocultural life. Religious practices, family life, the Creole language, and cultural materials that constitute the environment of the masses came to be sources of inspiration for this segment. Carrying on reflections initiated by some Haitian writers in literature, such as Frederic Marcelin, Price-Mars's publication *So Spoke the Uncle* launched an ethnographic program that placed at the center of investigation Haitian vodoun and its cosmology. In a larger regional context, the postslavery situation required a new approach on and understanding of "Black people" in White societies. In the United States and Brazil, the debate between Melville J. Herskovitz and Franklin Frazier about the impact of slavery on African American sociocultural life in the United States renewed discussions about Blacks' adaptation/assimilation in White-dominated societies. Later, Herskovitz took Haiti as a case in point to illustrate the survival of African cultural practices through religion, cultural materials, language, and traditions among Haitians. Herskovitz's team, comprising both

Haitian and American anthropologists, helped develop professional anthropological studies at the Bureau of Ethnology of Haiti, which later led to the creation of the Faculty of Ethnology at the State University of Haiti.

Haiti is a site, spatially, conceptually, and politically, of battle for the two anthropologies. The first is anthropology as a political discourse, the second anthropology as a discourse belonging to the field of science. The struggle lies in that they were originally one discourse, the second gradually emerging from the former, not least by the struggle to grasp what Haiti is. Today, current debates in Haiti are still self-consciously that of the second discourse taking account of the first, and also of the reality that the first racist discourse not only has currency in the politics of this hemisphere but also, at a deeper level, is still present in the second discourse in terms of the way in which it inflects the forms of supposition and misrecognition.

Although Haiti and Haitian sociocultural practices are, today, the object of study by many anthropologists from different perspectives in different languages, Haiti's excess of political turbulence, violence, socioeconomic degradation, and AIDS has provided new grounds for the resurgence of the notion of the state of exception. These foci illustrate the continuing symbolism of Haiti as representative "Blackness" (characterized in its radical negativity) in a world where race and racialization can be hinted at without having to cite it specifically. Hence, the evolution of political histories in terms of the evolution of a historically expository narrative that is mutually constitutive—Haiti and Europe/America—can only be imagined in terms of separate and sovereign spaces, which is itself a dimension of their mutual constitution, placing anthropology in a predicament for which it is still deciphering its own interpretations.

Since the beginning of excavation at this complex of mounds in 1920 to 1921, Harappa has remained the type site for the so-called Harappan Civilization, also known as “Indus” or “Indus Valley Civilization.” During the period from circa 2600 BC to 1900 BC, hundreds of settlements, some of them quite large, dotted the transborder region of northwestern India and eastern and southern Pakistan. Each of these Bronze Age sites has its own story, but in one way or another, they all shared a sophisticated and distinctive cultural tradition that continues to inspire archaeological research and impress visitors.

Years ago, scholars suggested that Harappa along with another famous Indus site, Mohenjo Daro (located circa 400 miles to the southwest), were twin capitals of an empire. More recent surveys and excavations indicate that Harappa was, instead, one of a number of urban centers (including Ganweriwala, Rakhigarhi, Dholavira, and Mohenjo Daro) that served as hubs, perhaps like city-states, in a vast network of local and long-distance trade, all of which depended on the region’s agricultural productivity. Harappans kept many species of domesticated animals, and various crops were grown, but wheat and barley were especially important. There is no hard evidence for irrigation, like that found in Egypt and Mesopotamia, but it is possible that floods destroyed such tangible remains or that the Harappans used less elaborate systems to divert water. This economic

network, which was concentrated in the alluvial plains of the Indus River and its tributaries, covered an area of at least 250,000 square miles and at least in size could be said to rival the territories united by rulers of ancient Egypt and Mesopotamia. The lack of historical accounts from this period and region makes it impossible to describe the political organization that created or protected this territory, or to explain precisely how a site like Harappa fits into the whole picture.

Harappa itself is located in northeastern Pakistan’s Punjab province, on the left bank of a dry bed of the Ravi River; the modern Ravi continues to flow about 6 miles north of the site. Named after the village that stands adjacent to the archaeological site (now represented by exposed and preserved ruins, as well as considerable unexcavated remains), Harappa’s ancient name remains unknown. Harappa was certainly one of the large towns of its day; the ruins cover an area of at least 375 acres. The site’s size is extremely difficult to determine because of thick deposits of alluvium that have covered ancient ruins. Population estimates for the ancient city vary widely, of course, with figures that range from 20,000 to 50,000.

Parts of Harappa were occupied from circa 3300 until perhaps as late as 1300 BC, a framework much longer than the period to which the site has loaned its name. This history has been subdivided into various periods through the careful study of the site’s stratigraphy and a large number of radiocarbon dates. This is especially important, since the site of Harappa has yielded occupational evidence from the entire seven centuries spanned by the Indus civilization, a further justification for its role as a type site. Changes in Harappa’s material remains are obvious over this period of 20 centuries, but there is enough continuity to suggest that this ancient city, and the civilization named after it, developed internally and probably declined as a result of natural occurrences (for example, shifting river courses, floods), including the dessication of the Ghaggar-Hakra drainage system. Nowadays, fewer scholars attempt to explain the rise and fall of the Indus civilization with reference to invasion and migration (for example, the Aryan invasion).

The ongoing research at the site is multidisciplinary in scope and continues to refine the site’s occupational history and to address topics like ecology, agriculture, and procurement of resources. The

modern excavations at Harappa rest on the pioneering efforts of both local and British scholars, including the important contribution made by Mortimer Wheeler.

During the current phase of research at Harappa and in the region at large, new data and sites have been discovered, and earlier interpretations of various architectural features have been called into question. For example, Wheeler's identification of a fortified "citadel" on Harappa's western mound (Mound AB) has been questioned by many scholars. What he and other scholars called a "granary" has been identified by others as a palace, and the function of large circular platforms near the "granary," once identified as a grain processing area, is still open to debate. Streets and housing blocks followed a well-organized grid plan. Extensive use of baked bricks and the construction of wells and a drainage system also reflect the talents of the Bronze Age planners in Harappa.

Like the other cities in the Harappan realm, the affluent classes of this city acquired luxury products through exchange with distant lands, through a system of overland and maritime trade. Prized imports included gold, silver, copper, carnelian, lapis lazuli, and turquoise. Objects from the Indus Valley have turned up at distant sites in India and in Mesopotamia. Wheel-made pottery and terra cotta figurines and the occasional piece of sculpture in the round reflect an aesthetic flair, but the real artistic accomplishment of the Harappans is seen in their small, square-stamp seals (most of them carved in steatite). These were used to show ownership and have been found in large numbers; they are the principal medium for the 4,000 brief inscriptions in the still indecipherable Indus script. Though no temple has been identified at any Indus civilization site, insight into Harappan mythology and religion may be provided by some intaglio scenes on these steatite stamps, which display other plant, animal, and human figures.

The Indus civilization and each of its component sites are a virtual laboratory for the investigation of early political and economic centralization and decentralization. Sites like Harappa contain valuable data for studying continuity and change within a regional context, in south Asia and beyond.

HARDY-WEINBERG PRINCIPLE

Darwin's theory of evolution by natural selection requires heritable variation for selection to work on. In Darwin's time, thinking about heritability centered on the idea of "blending inheritance"—the hypothesis that the offspring receive some average mix of the parental characters. If this were true, each generation would be more average than the last and variation would steadily decline. To make natural selection work, Darwin had to suppose that the frequency of mutations—"sports" as they were often called—was high.

In 1900, the pioneering work of Gregor Mendel was independently rediscovered by Hugo De Vries, Carl Correns, and Erich von Tschermak-Seysenegg. Mendel had proposed that each character is controlled by two genetic factors (genes), one from each parent. Most characters have a dominant form and a recessive form (phenotype). The different phenotypes result from different versions of the gene, called alleles, whether they are the same or different in the two chromosomes. The dominant phenotype is expressed when one or both alleles are dominant; when both alleles are recessive, the recessive phenotype is seen.

It was not immediately obvious that Mendel's model had anything to say about evolution; biologists assumed that dominant alleles would slowly displace their recessive counterparts, thus inexorably reducing variation. In 1908, however, G. H. Hardy and W. Weinberg independently realized that Mendelian inheritance would, in fact, maintain variation at current levels under most circumstances.

The conditions necessary for this Hardy-Weinberg equilibrium in a sexually reproducing population are:

1. The population needs to be large; otherwise, chance effects could lead to genetic drift—a random change in allele frequencies that usually leads to the local extinction of one of the two alleles.
2. Mutations must not be common, since mutations produce new alleles.
3. There must be no immigration or emigration that alters allele frequency.
4. Mating must be random with respect to alleles.
5. Reproductive success must be random with respect to alleles.

If any of these conditions is violated, evolution (a change in allele frequency) will occur. Violation of condition 5, of course, is the essence of natural selection. (Condition 4, which Darwin called “sexual selection,” is only a special case of condition 5.)

The Hardy-Weinberg formulation not only accounts for how variation is maintained, it identifies alternative mechanisms for evolution—genetic drift, for instance. What Hardy and Weinberg could not know at the time is that most genes are pleiotropic; that is, each has multiple effects of the phenotype. Moreover, most phenotypic characters are controlled by a combination of many genes. Each of these genotype/phenotype interactions helps preserve variation. In addition, sexual recombination operates to produce a nearly infinite number of novel combinations of alleles in each generation.

HARLOW, HARRY F. (1905–1981)

Harry F. Harlow is best known for his studies of mother love and the importance of social interaction in primate learning. He was born in Fairview, Iowa, in 1905. He received his BA and PhD in psychology from Stanford University and immediately joined the

faculty at the University of Wisconsin, where he established the Psychology Primate Laboratory. It expanded and merged with the Wisconsin Regional Primate Laboratory in 1964, with Harlow as its director. The Wisconsin Primate Center drew in several leading scientists, including humanistic psychologist Abraham Maslow.

Harlow questioned current theories, which stated that love was a function of the feeding bond between mothers and a means of regularizing sexual contact. To examine the significance of mothering and the universal need for contact, Harlow studied baby rhesus monkeys, because they demonstrated a range of emotions similar to human babies and needed to be nursed. In his famous “wire mother study,” Harlow took infant monkeys away from their biological mothers and assigned them to two wire surrogate mothers. One model was made entirely out of chicken wire and had a bottle with a nipple that could feed the baby monkeys. It also had an electric light for warmth. The other model was made of soft cloth but did not have a light or a bottle. Harlow observed that the babies rarely stayed with the wire model any longer than it took for them to feed, but they cuddled with the softer cloth model, especially if they were frightened. When Harlow outfitted the cloth model with the bottle of food, the baby rhesus refused to go to the wire model at all. Harlow also observed that in times of fear, it appeared that the cuddling between “mother” and baby was stronger than the physical drive to feed or the need for warmth. Baby monkeys would cling to the cloth mother for days instead of eating if a fear stimulus was added to the cage. Harlow concluded that cuddling with the cloth model provided the babies with a sense of safety and security that was more important to them than the feeding bond.

Harlow’s studies also found that young monkeys reared with live mothers and young peers learned social skills faster than those reared with cloth mothers, although they appeared to catch up socially in about a year. Harlow also found that babies raised by biological mothers but with no playmates were socially incompetent, demonstrating fear or aggression toward other young monkeys. This also affected their ability to mate successfully. In addition, females who did not develop social competency and who had babies were very neglectful of them. They did not seem to know how to create secure attachments with them. From these studies, Harlow concluded that sex

alone did not organize societies. He also concluded that mother love was not sufficient to enable individual social relations. And Harlow argued that although children need love and affection from a caregiver, early childhood social development is dependent on a wide range of emotional ties with both family and peers.

Harlow's provocative theories regarding normal sexual and parental behavior furthered the scientific study of love. His empirical research made significant contributions toward understanding general and child behavioral development in the areas of learning, motivation, and affection. His work contributed to the field of anthropology because he showed that humans can learn strategies from one another to solve problems, contributing to their ability to adapt to a wide range of stimuli.

Dr. Harry Harlow died in 1981. He served as President of the American Psychological Association, 1958 to 1959. He earned the National Medal of Science in 1967 and the Annual Award from the Society for the Scientific Study of Sex in 1972. He was a member of the National Academy of Sciences and the National Academy of Arts and Sciences.

HARRIS, MARVIN (1927–2001)

Marvin Harris is one of the most prominent contributors to 20th-century anthropological theory. He is best known as the originator of cultural materialism, a theoretical paradigm and research strategy aimed at providing causal explanations for differences and similarities in cultural behavior. Cultural materialism assumes that cultural patterns are ultimately derived from the practical problems of human existence.

Born in Brooklyn, New York, Harris received his undergraduate and graduate training at Columbia University, where he earned his PhD in 1953. He taught at Columbia for nearly three decades, and from 1980 until his retirement in 2000, he was graduate research professor of anthropology at the University of Florida.

Like others in his student cohort in the Department of Anthropology at Columbia, Harris was trained in the four subfields of the discipline. His first exposure to anthropology came in Columbia's introductory course taught by Charles Wagley, who later became his mentor. The course took a four-field approach, and according to Harris, the basic outline of the course could be traced back to Franz Boas, the dominant figure in the Columbia department as well as in American anthropology for the first half of the 20th century. Although Harris was a severe critic of Boas's method for studying culture, he was a staunch defender of Boas's vision of four-field anthropology and of the Boasian stance on race, language, and culture. As a result of his early training, Harris addressed large questions in and across the subfields of anthropology throughout his professional career.

The Rise of Anthropological Theory

The impact of Marvin Harris's ideas can be gauged from his 1968 magnum opus, *The Rise of Anthropological Theory*, an overview of anthropological theory from the perspective of cultural materialism. Harris introduced the term *cultural materialism* in this volume—"the Rat," as it is known to three generations of anthropology students. The book's contribution to anthropological theory was highlighted in 1991, when both the Social Science Citation Index and the Arts and Humanities Citation Index named it a "citation classic."

In the book, Harris argued that previous social theorists had never developed an entirely satisfactory materialist and nomothetic (generalizing) research strategy dedicated to explaining the evolution of sociocultural differences and similarities. As such, the yardstick he used to evaluate specific theories and schools of thought was the degree to which they aided an understanding of and provided explanations for cross-cultural variation.

The Rat is truly a history of anthropological theory. Through the lens of cultural materialism, it analyzes individual theories and schools of thought

from the 18th century through the 1960s. It begins with the Enlightenment, the era Harris identifies as the one in which naturalistic causal explanations of cultural phenomena were first established, a modern conception of culture began to evolve, and materialist explanations of cultural similarities and differences first appeared. Harris explores the subsequent reaction against naturalism and materialism in the early 19th century and their eventual replacement by hard-core biological determinism that, with the notable exception of Marxist materialism, held sway over anthropological theory into the early 20th century. Franz Boas and his followers rescued anthropology from biological reductionism only to replace it with an idiographic strategy that, from Harris's perspective, did little to advance anthropology as a scientific enterprise.

The Rat concludes its theoretical journey with discussions of neoevolutionist and ecological approaches to the study of culture, both of which Harris believed came closest to the cultural materialist paradigm he was championing. While admiring his nomothetic cultural evolutionary approach, Harris faulted anthropologist Leslie White for his lack of interest in environmental variation. The anthropologist treated most favorably in the work was Julian Steward, whose combined interests in cultural evolution and cultural ecology and whose concept of culture core came closest to Harris's own model of technoenvironmental, technoeconomic, and demographic determinism.

A central theme of the volume was the critique of what Harris saw as prevailing idealist and idiographic schools of thought in anthropology. The ongoing influence of such paradigms in contemporary anthropology, which he eventually analyzed in their various transformations—symbolic and interpretive anthropology, structuralism and postmodernism—concerned Harris throughout his career. His last book, *Theories of Culture in Post-Modern Times* (1998), was a series of essays debunking such approaches to the study of culture.

Cultural Materialism

Although the *The Rise of Anthropological Theory* used cultural materialism as a framework for evaluating previous theories, the full elaboration and defense of Harris's materialist paradigm was realized in *Cultural Materialism: The Struggle for a Science of Culture* (1979). Cultural materialism evolved from and was

influenced by a number of theoretical currents including evolutionary theory, cultural ecology, and Marxist materialism. Harris acknowledged his debt to all of them, most especially the latter. But he emphatically differentiated his own model from *dialectical* materialism as well as from the program for political action that is so closely associated with Marxist materialism.

Cultural materialism “is based on the simple premise that human social life is a response to the practical problems of earthly existence” (Harris, 1979, p. ix). This statement highlights the central tenet of cultural materialism, infrastructural determinism, the assumption that explanations for cultural similarities and differences ultimately lie in the material conditions of human life. A society's infrastructure (or material base) is its system of production and reproduction, which is determined by a concatenation of ecological, technological, environmental, and demographic variables. The study of a society's infrastructure investigates “how people obtain food and shelter, maintain a population base, and satisfy other basic biological and emotional needs and drives” (Harris & Johnson, 2000, p. vi).

A society's infrastructure, in turn, shapes its structure and superstructure. A society's structure comprises its domestic economy (social organization, kinship, division of labor) and its political economy (political institutions, social hierarchies), while its superstructure consists of the ideological elements of culture, its religious, symbolic, and artistic and intellectual activities.

The study of infrastructure should be a “strategic priority” because it is “the principal interface between nature and culture,” according to Harris; if the goal of science is to establish lawlike generalizations, then one should begin by studying those aspects of sociocultural systems “under the greatest direct restraints from the givens of nature” (Harris, 1979, p. 57). But contrary to some of his critics, Harris does not hold that all changes in sociocultural systems stem from alterations in their infrastructures, nor does he suggest that structure and superstructure are mere passive reactors to shifts in a culture's material base. Nevertheless, if structural or superstructural changes are not compatible with the existing modes of production and reproduction, they are unlikely to persist and spread.

In sum, cultural materialism holds that over time and in most cases, changes in a society's material base

will lead to functionally compatible changes in its social and political structures, along with modifications in its secular and religious ideologies. The ultimate goal of cultural materialism is to explain, not merely describe, cultural variations in the way people live.

As part of this model, Harris distinguished emic and etic approaches to cultural data. In an emic approach, the observer learns the cultural rules and categories from the native's perspective. If informants agree on a description or interpretation of data, the data are considered accurate. With an etic approach, in contrast, the observer does not use native rules or categories, but rather those derived from independent observers using agreed-on scientific measures. Quantifiable measurements such as fertility rates, caloric intake, or average rainfall are employed in order to develop general cultural theories without regard to whether those measurements "mean" anything to the native populations themselves. Harris argued forcefully that a science of society cannot be based solely on informants' interpretation of their own behavior.

Harris also viewed cultural materialism as a vehicle for understanding and solving contemporary social problems. After all, before problems like poverty and racism can be solved, their causes must be understood. In his words, "If it be anthropology to struggle against the mystification of the causes of inequality and exploitation, long live anthropology" (Harris, 1979, p. 340).

Cultural Materialism Applied: Research in Brazil, Mozambique, and India

Harris's field research, most of which was guided by the principles of cultural materialism, took him to three continents; he worked in Brazil, Mozambique, and India. His early Brazilian research resulted in *Town and Country in Brazil* (1956), an ethnographic study of Minas Velhas, a historic mining community in Bahia state. Harris provided a vivid description of racial prejudice in Minas Velhas, but he also showed that prejudice did not necessarily translate into systematic discrimination, taking issue with the notion that attitudes and temperament are the best predictors of behavior.

Source: Photo by Susan Harris, courtesy of the University of Florida, Department of Anthropology.

Harris's work on race and race relations received its fullest treatment in *Patterns of Race in the Americas* (1964), in which he used a cultural materialist framework to systematically compare the divergent racial patterns that emerged in Brazil, the United States, the Caribbean, and highland Latin America. Here, Harris took issue with cultural heritage and national character explanations of racial patterns, particularly those advanced by Brazilian social theorist Gilberto Freyre. Freyre had stressed the role of Portuguese national character in forming Brazilian race relations, and indeed in creating a "new world in the tropics" based on a penchant for racial tolerance and miscegenation. In *Patterns of Race in the Americas*, Harris argued persuasively for the role of material conditions in forming the patterns of race in different parts of the Americas. And he debunked Freyre's contention that slaves received more humane treatment in Brazil than in the United States, supposedly because of differences in Portuguese and Anglo national character, religion, and attitudes toward darker-skinned peoples.

Harris is also known for his work on Brazilian racial classification, especially his research on the multiple racial categories in everyday use throughout Brazil. To understand how racial classification and behavior in regard to race differed in Brazil and the United States, Harris and anthropologist Conrad Kottak coined the term *hypo-descent*. Because a rule of hypo-descent exists in the United States, children of mixed parentage, that is, those from a union of an African American and a Euro-American,

are always assigned to the minority category. But hypo-descent is absent in Brazil, where racial classification is based more on individual phenotype and social perceptions than on parentage. Harris concludes that the evolution of these different systems of racial classification arose out of the material conditions of divergent settlement and subsequent histories of Brazil and the United States.

In his last field research in the early 1990s, Harris returned to Brazil and to the issue of Brazilian racial classification. This time, he contrasted the categories used by Brazilians themselves in designating their own race and the racial categories employed in the Brazilian census. Because of differences in the racial terminology used in each instance, Harris found that Brazilian census data overestimated the White segment and underestimated the mixed-race segment of the national population.

Harris traveled to Mozambique, then a Portuguese colony, in 1955 to 1956 to study acculturation among the Ba Thonga people. However, after his arrival in Mozambique, Harris became more interested in politics and did not complete his planned fieldwork. He became good friends with the academic Eduardo Modlane, the leader of Frelimo, the Mozambique liberation movement, who later became the first president of an independent Mozambique. Advocating Mozambican independence from Portugal, Harris wrote *Portugal's African Wards* (1958). Harris's field study in Mozambique and his subsequent denunciations of the plight of Africans under Portuguese rule were influential in the eventual abolition of the forced-labor system in use there.

Harris's fieldwork in India was inspired by the reading he did for his article "The Cultural Ecology of India's Sacred Cattle," published in *Current Anthropology* (1966). Again attacking the primacy of the ideological over the material, Harris demonstrated the many roles that sacred cattle play in the Indian ecosystem. He interpreted Hindu doctrine as using the full force of religion to help conserve a vital resource, the sacred cow.

Cultural Materialism for a Wider Audience: Popular Writings

Harris published 19 books, collectively translated into 14 languages. He applied his theoretical principles in several popular books written in a compelling, accessible style. In all of them, Harris turned his materialist

gaze on and attempted to provide scientific explanations for what he called "the riddles of culture," an approach that made him both highly influential and controversial. He also employed a materialist paradigm in writing two widely used introductory textbooks that have gone through several editions each, *Culture, People, Nature* (1997) and *Cultural Anthropology* (with Orna Johnson, 2002).

Cows, Pigs, Wars, and Witches (1974), arguably the most persuasive and prominent of his popular books, was the first one written for a general audience. It was inspired by Harris's fascination with the sacred cow in India as well as other puzzling cultural phenomena such as religious dietary restrictions (including the Jewish and Muslim taboos against eating pork), cargo cults, and witch hunts.

This was followed by *Cannibals and Kings*, which took a historical view of some of the cases examined in *Cows, Pigs, Wars, and Witches*. But Harris also extended his inquiry to new riddles of culture. One of the most controversial was his analysis of Aztec cannibalism, which Harris interpreted in the context of protein shortages resulting from the lack of significant animal domestication in Mesoamerica.

Good to Eat (1985) was a critique of anthropologist Claude Lévi-Strauss's contention that classificatory systems involving animal food taboos could be understood mainly because they were "good to think." To the contrary, Harris argued, a better approach is to see animals first as food for the body rather than for the mind. Harris's popular books showed an enduring fascination not only with Lévi-Strauss but also with the Yanomamo Indians of Venezuela and Brazil, as described by anthropologist Napoleon Chagnon. Harris rejected Chagnon's initial sociopolitical explanation for Yanomamo warfare, as well as Chagnon's subsequent use of explanatory models from human evolutionary ecology. Harris insisted that protein shortages provided the best explanation for the "riddle" of Yanomamo raiding patterns.

Our Kind completes a quartet of Harris's books aimed at explaining the riddles of culture to students and an educated lay audience. Harris's renown beyond academic circles spread through these readable, intriguing, and controversial works. Harris liked to compare the riddles of culture to potato chips: No one can eat just one. That is, whenever he offered a solution for one riddle—the sacred cow, for example—someone would say, "Yes, but what about the abominable pig or primitive warfare?" Of the

books in the quartet, *Our Kind* is most like a bag of potato chips. In it, Harris provides very short explanations for dozens of cultural riddles.

In *Why Nothing Works* (1987), Harris moved from the study of cultural riddles in “exotic” societies to an analysis of shifts in the material base of his own society. Here, he sought to highlight and explain the deficiencies of an economy changing from heavy goods manufacture to services and information. Employing a well-reasoned cultural materialist analysis, Harris showed how changes in the American economy were reflected in shifts in the nation’s social organization—its marriage and family patterns, gender roles, and sexual relations—and its attendant ideology.

The influence of Harris’s theories was not limited to cultural anthropology. As archaeologist David Hearst Thomas has noted, “roughly half of the practicing American archaeologists consider themselves to be cultural materialists to one degree or another.” As a result of the forcefulness of his ideas elaborated in his many publications, Marvin Harris’s theoretical paradigm has become one of the best known in contemporary social science.

HARRISSON, BARBARA (1922–)

Barbara Harrisson is an art historian, archaeologist, and naturalist renowned for her work on primate conservation and the prehistory of Borneo. Born into a German family in Silesia, Poland, her early academic studies were interrupted by the events of World War II. From 1953 to 1972, she conducted research in Borneo, mostly in collaboration with her husband, Tom Harrisson, curator of the Sarawak Museum. During this period, she was actively involved in primate conservation, especially with the rehabilitation of captive and orphaned orangutans and their reintroduction into the wild. The results of this work were published in her popular book *Orang-utan* (1962) and in *Conservation of Nonhuman Primates in 1970* (1971). For her contributions to primate conservation she was awarded an honorary DSc from Tulane University in 1973.

Harrisson is best known, perhaps, for her investigations into the prehistory of Borneo, particularly her research with Tom Harrisson at Niah Cave in Sarawak. Excavations at Niah from 1954 to 1967 yielded extensive archaeological remains and a series of human burials dating back to the late Pleistocene. It still represents the most complete archaeological record documenting the prehistory of the region. Harrisson excavated and described the human burials from Niah and published research on the imported ceramics. The oldest human material from Niah, the so-called Deep Skull, was recovered from “Hell” trench in 1958, associated with Paleolithic stone tools and charcoal dated by carbon 14 to older than 40,000 years before present. Although some doubts have been raised about the validity of the dating, it is likely that the find does represent the oldest modern human from Southeast Asia. The cranium belonged to that of a young adult female, closely resembling those of native people today from Australia and Melanesia.

Harrisson’s most recent research has focused on Asian trade ceramics, which led to the publication of *Later Ceramics in South-East Asia: Sixteenth to Twentieth Centuries* (1995) and *Pusaka: Heirloom Jars of Borneo* (1999). In 1977 she was appointed director of the National Ceramic Museum in The Netherlands, the Princessehof in Leeuwarden, in which capacity she served until her retirement in 1987.

 HEALTH CARE, ALTERNATIVE

The developed world has transformed from industrialized societies organized around the production of goods by machines into technocracies: societies organized around evolution through the development of sophisticated technologies and the global flow of information through these technologies. Thus, Davis-Floyd has labeled its dominant health care paradigm “the technocratic model of medicine” to highlight biomedicine’s precise reflections of technocratic core values. The technocratic model emphasizes the separation of mind and body and metaphorizes the body as a machine and the patient as an object (“the gall bladder in 212”). The resultant mechanicity and often impersonal nature of biomedical care have been mitigated in recent years by increasing emphasis on humanism within biomedicine. The “humanistic model” stresses the importance of “mind-body connection,” defines the body as an organism, and sees the patient as a relational subject; it views the relationship between patient and practitioner as an essential ingredient of healing. While encompassing the relational values of humanism, most alternative healing methods are ideologically grounded in a third transnational paradigm, the “holistic model of medicine,” which recognizes mind, body, and spirit as a whole, and defines the body as an energy field in constant relation to other energy fields, demanding attention to energy-based healing—a radical departure from the mechanistic approach of biomedicine.

The holistic “revolution” has arisen within the technocracy but outside of technomedicine in the United States since the 1970s, driven by a wide variety

of nonallopathic practitioners and consumer activism. In European countries, holistic, energy-based treatments, such as homeopathy (all but eliminated in the U.S. in the early 1900s), have been available and widely used for over a century. In the developing world, many elements of traditional and indigenous healing systems are increasingly being incorporated into holistic or alternative health care. Concomitantly, indigenous folk practitioners are actively expanding their knowledge bases to incorporate elements of internationally known alternative methodologies into their folk practices. Such folk practitioners recognize a continuity of ideology between their own traditions (which often include appreciation for the “spirit” or “energy” present in a wild herb, an attentive massage, or a shamanic encounter) and the ideologies behind internationally known alternative systems like homeopathy, reflexology, moxibustion, and iridology.

At present, a small percentage of physicians worldwide define themselves as “holistic,” but in general, biomedical practitioners have been resistant to accepting other knowledge systems as valid and continue to regard their own system as exclusively authoritative. Nevertheless, as the limits of biomedicine (which cannot cure many common ailments) become increasingly evident, millions of people continue to rely on or are beginning to revalue indigenous healing systems and to incorporate holistic or “alternative” modalities into their care.

Various terms have been bandied around over the past several decades for this wide array of heterodox health care systems, which range from professionalized to folk/indigenous. In Australia, for example, the most commonplace term for these is simply *complementary medicine*; in the United States, it is *complementary and alternative medicine* (CAM), although many proponents prefer the terms *holistic* or *integral* medicine to avoid the connotations of inferiority to biomedicine that the other terms entail. Medical anthropologists have tended to focus on various folk medical systems, such as *curanderismo* or *espiritismo*; more recently, a growing number have studied professionalized heterodox medical systems, such as chiropractic, naturopathy, and direct-entry midwifery, as well as biomedical physicians and nurses who utilize alternative therapies.

The medical systems of all complex societies today, from India to Indonesia, Brazil to Bangladesh, consist of both biomedicine and alternative systems that coexist in generally competitive, sometimes collaborative,

and sometimes co-optive relationships. This *medical pluralism* is characterized by a pattern in which biomedicine exerts dominance over alternatives, professionalized or not. Patterns of medical pluralism tend to reflect hierarchical relations in the larger society based upon class, caste, racial, ethnic, regional, religious, and gender divisions.

The U.S. medical system, for example, consists of several levels that reflect such hierarchies. In rank order of prestige, these include (1) biomedicine; (2) osteopathic medicine as a parallel medical system, focusing on primary care and incorporating spinal manipulation as an adjunct; (3) professionalized heterodox medical systems (chiropractic, naturopathy, acupuncture, and Chinese medicine); (4) partially professionalized or lay heterodox medical systems (for example, homeopathy, herbalism, bodywork, and direct-entry midwifery); (5) Anglo-American religious healing systems (for example, Spiritualism, Christian Science, Pentecostalism, and Scientology); and (6) folk medical systems (for example, southern Appalachian herbal medicine, African American folk medicine, *curanderismo* among Mexican Americans, and Native American healing systems). With some modification, this dominative model can be applied to other modern societies. For example, whereas medical doctors (MDs) tend to be upper- or upper-middle class and male, folk healers tend to be working-class members of various ethnic groups. Alternative medical systems often exhibit counterhegemonic elements that resist, often in subtle forms, the elitist, hierarchical, and bureaucratic patterns of biomedicine.

New medical systems or synthetic ensembles of therapies often emerge as popular health movements that undergo a process of professionalization that may open them to biomedical cooption. The holistic health movement in the United States began as a popular movement that challenged the bureaucratic, impersonal, and iatrogenic aspects of biomedicine. Far from monolithic, it encompassed numerous alternative medical systems (listed above). Although the philosophical premises of each of these are divergent, they share in common the holistic definition of the body as an energy field responsive to treatment from the energy in the herb, the homeopathic remedy, the Reiki treatment, and the chiropractic adjustment. Practitioners of such modalities today can be found in almost every country.

Beginning in the late 1970s, an increasing number of biomedical practitioners began to adopt alternative

therapies for two reasons: (1) recognition of the limitations of the biomedical paradigm and (2) loss of many of their more affluent patients to alternative practitioners. More and more biomedical schools have begun to offer courses on alternative medicine as it became apparent that the “bread-and-butter” patients of biomedicine, those with disposable incomes, could afford to pay for alternative therapies out of their pockets. In a sense, the alternative health care movement has won its battle, and medical pluralism instead of biomedical dominance is the norm of the day in most contemporary technocratic societies.

In most countries, biomedical practitioners accept the existent medical plurality in their countries, yet work to remain hegemonically reinforced by government policies that pay for medical, and not alternative, care for their citizenry. In the United States, biomedicine has fought back by working at various times to remove herbal supplements from health food store shelves, to incriminate particular holistic practitioners, and to prevent insurance companies from paying for alternative care. Nevertheless, today over one half of all Americans utilize some form of CAM. Around the world, health insurance companies, health maintenance organizations, hospitals, and national governments have become increasingly interested in alternative therapies as a way of satisfying patients’ demands and curtailing costs.

When CAM is systematized, although its practitioners often continue to adhere to some notion of holism, it can come to function as a style of health care in which biomedicine treats alternative therapists as subordinates and alternative therapies as adjunct. Some have even argued that alternative medicine in various national contexts is being co-opted by biomedical institutions, including centers of integrative medicine, biomedical schools and hospitals, the NIH (National Institutes of Health) National Center for Complementary and Alternative Medicine, and allopathic physicians who advertise themselves as “holistic” because they prescribe a few herbal supplements along with pharmaceutical drugs.

In contrast to the examination of indigenous or folk medical systems, the anthropological study of professionalized alternative health system remains in its infancy. Much remains to be learned about the specific ideologies behind each alternative system, the efficacy of its treatments and to what extent that efficacy depends on cultural or individual belief, and

what happens to them in practice when professionalization and integration into “the system” occur.

HEATH, SHIRLEY BRICE

Shirley Brice Heath is professor emeritus of linguistics and English at Stanford University and has made significant contributions to both cultural and linguistic anthropology. Her focus is primarily within the United States, but she has also taught and carried out research in such diverse settings as Stockholm, Johannesburg, and Papua New Guinea. Her deeply engaged, longitudinal studies across a variety of cultural and institutional settings have contributed greatly to anthropology's understanding of children and youth in postindustrial societies, as well as to the role of language, cognition, and organizational structures in learning. The common thread among her various foci has been a concern for how the linguistic practices of children and youth from subordinated groups contribute to the development of learning and identity, both within and beyond school.

Though she has also written on the history of language policy in both the United States and Latin America, Heath is best known for her classic ethnography *Ways With Words*, which has become a standard work in university courses in ethnography of speaking and educational anthropology. *Ways With Words* examines in vivid detail how children from two neighboring communities in the southeastern United States learn to use language at school. It combines insights from child development and language acquisition, literacy studies, anthropology, and social history to contrast the linguistic practices of two

working-class communities, one African American (Trackton) and one White (Roadville), and to show how both differ from the practices of the “mainstream” townspeople (White and Black), who hold social and political power in the region. Heath's analysis of the uses of literacy and oral narrative in both communities sheds light on how cultural differences manifest themselves as communication problems in school settings, with unfortunate results for working-class students. The book stresses possibilities for bridging the cultural differences between home and school, while also recognizing the structural and institutional constraints that make this difficult.

Like much school ethnography from the 1970s and 1980s, *Ways With Words* locates the principal causes of minority school failure in the cultural differences between mainstream and minority groups, rather than in political-economic structures or racist ideologies. This has been grounds for criticism from anthropologists of a more explicitly political bent; nevertheless, the work remains a touchstone of linguistic and educational anthropology for its detailed comparative analysis of the communicative practices of neighboring social groups and how these practices lead to social stratification over the course of students' educational careers.

Heath later turned her attention to learning among older adolescents in nonschool contexts, with particular attention to young people's involvement in community organizations and the arts. She directed the prize-winning documentary *ArtShow*, which has been shown in numerous prestigious galleries in the United States and Europe. The film, which is accompanied by a book/resource guide, highlights the ways in which certain kinds of organizations can aid young people in challenging the public perception of youth as apathetic, disengaged, and “at risk.” Intended for a broader audience than most of her scholarly work, *ArtShow* continues and expands Heath's focus on the symbolic representations and linguistic practices of youth, showing how culturally based programs in the arts can help youth “practice adulthood” while they develop their own leadership and initiative in solving problems within their communities. In this, as in other studies, Heath has made a point of including her young research subjects as members of the research team.

HEGEL, G. W. F. (1770–1831)

Georg Wilhelm Friedrich Hegel was born on August 27, 1770, in Stuttgart, Germany, and died on November 18, 1831, in Berlin. He was born into a family of Swabian civil servants. In 1783, his mother, Christine Luise Hegel, neè Fromm (1741), died. After successfully completing his school exams at *Gymnasium illustre*, he started studying at the famous Tuebinger Stift in autumn 1788. He took courses in philosophy, classics, and mathematics, and received an MA in philosophy, which was regarded as equivalent to a doctorate at other universities in 1790. From 1790 to 1793, he studied for and passed a further exam in theology.

Among his friends and fellow students were Friedrich Wilhelm Joseph Schelling and Friedrich Hölderlin. It has to be noted that Hegel was pensive and precocious, and he was referred to as “the old man” when he was still a student. Throughout his life, he remained clumsy, and he was a poor public speaker. After successfully finishing his studies in autumn 1793, he started working as a private tutor (*Hauslehrer*) in Bern, Switzerland, where he remained until 1796. From January 1797 until 1800, he lived as a private tutor in Frankfurt am Main. An inheritance enabled him to give up his post as a tutor, and he moved to Jena in the beginning of 1801, where his friend Schelling as a successor of Fichte lectured in philosophy.

In summer and spring 1801, Hegel wrote a thesis (Habilitation, postdoctoral qualification, necessary condition for lecturing in Germany, connected to the *venia legendi*) on the orbits of the planets (*De orbitis planetarum*), which comprises only about 25 pages

and which he defended on August 27, 1801. In the same year, he also published his first philosophical work, *Differenz des Fichte’schen und Schelling’schen Systems der Philosophie*. Schelling and Hegel frequently cooperated and edited a philosophical journal (*Kritisches Journal der Philosophie*), which was, however, discontinued after Schelling left Jena in 1803. In 1805, Hegel was appointed as a sort of associate professor (*außerordentlicher Professor*) by Goethe, who was the acting secretary of state.

During his time in Jena, Hegel wrote his first main work, *Die Phaenomenologie des Geistes* (1807), and he also fathered an illegitimate son with his landlady, Christiana Charlotte Burkhardt, neè Fischer (Jena), who before had two children by two other lovers. As a result of financial problems, he gave up his position in Jena and became first the editor of the *Bamberger Zeitung* (1807), and then the headmaster of a high school in Nuremberg (1808). There, he married Maria Helena Susanne von Tucher, who was 22 years his junior. Together they had two sons. A daughter died shortly after being born, and there were two miscarriages. While Hegel taught in Nuremberg, he wrote *Die Wissenschaft der Logik* (1812–1816, 2 vols.). In 1816, he accepted the offer to teach at the University of Heidelberg, and while he was there, his work *Encyclopaedie der philosophischen Wissenschaften* came out (1817). In 1818, he accepted the offer of the chair in philosophy at the University of Berlin, which was formerly occupied by Fichte. His work *Grundlinien der Philosophie des Rechts* came out in 1820. He died on November 18, 1831, in Berlin, during a cholera epidemic. The first edition of his complete works was published from 1832 to 1845. Although this edition was very influential, it is not very reliable.

Theory

The three most fundamental realms of Hegel’s philosophy are the realms of logic, nature, and spirit. Even though he distinguishes between nature and spirit, these realms are connected within a monist metaphysics. His understanding of logic is also different from our understanding of logic as it is taught in symbolic logic courses. Logic, according to Hegel, is the science of reason, and reason is both a human as well as an ontological ability, in the same way, as according to Heraclitus, the world is governed by the Logos, and we human beings grasp this by means of our Logos. Within the discipline of logic, Hegel presents his

Source: Courtesy of the Library of Congress.

theory of categories. Hegel distinguishes between subjective and objective logic. Objective logic deals with notions such as “being,” “nothingness,” “becoming,” “cause and effect,” “necessity,” and other abstract notions. He bases his analysis on the assumption that to each category, there is another one opposed to it, which upon closer inspection reveals that it is part of the meaning of the original category. Subjective logic, on the other hand, is concerned with the theory of notions, judgments, and inferences. Within his discipline of logic, Hegel also presents his dialectical method, which he himself often refers to as speculative method, which represents a very difficult if not problematic aspect of his philosophy, since one of the premises of this method is that all things are in themselves contradictory. The dialectical movement starts from something, then via the negation of that, something comes to something else, whereby the

something else may not be nothing, and via a further negation, or absolute negation, reaches a further beginning. This movement is often described as leading from thesis to antithesis and then synthesis; however, this is not how Hegel described the method. It is one of the tasks of logic to get to know the realms of nature and spirit, as the absolute idea that encloses these two realms is the main topic of logic. As his highest definition, Hegel puts forward the absolute as spirit. However, as the absolute is an all-inclusive process, it as a whole is not only spirit but also nature.

In his philosophy of nature, Hegel is concerned with forces, laws, and types. The realm of the spirit is divided up into the realm of the subjective, objective, and absolute spirit. The subjective spirit comprises anthropology, and psychology, the objective spirit, law, and morality, and the absolute spirit, art, philosophy, and in particular religion. The realm of nature is linked to causality and the realm of spirit to freedom. Nevertheless, according to Hegel, these two opposite realms are united in a monistic metaphysics. It might help to know that his metaphysics bears some similarities to the neoplatonic systems, in which the one, the *hen*, which is the origin of everything, flows over and brings about *nous*, the realm of the spirit, and *physis*, the realm of nature.

Hegel applied his basic insights to various topics. He was also concerned with history. In his philosophy of history, Hegel gives an overview of the whole of world history from early civilizations to the French Revolution and his own times. Thereby, he interprets history by means of his own basic concepts as, according to Hegel, everything in history happened for a certain purpose and had a specific meaning and significance: “The history of the world is none other than the progress of the consciousness of freedom.”

“True history,” according to Hegel, begins in early Persia, where the ruler justified his position by reference to a general spiritual principle instead of accepting it just as a natural fact. This represents the beginning of the growth of the consciousness of freedom. When the Persian Empire attempted to expand its realm and defeat the Greek city-states, and the city-states of ancient Greece won, the focus of world history was also passed on. In Ancient Greece, some people, the citizens, were free, whereas in the oriental world, only one, the leader, was free. This shows that the idea of freedom then was still a limited one. In addition, the Greeks and the Orient people lacked the concept of individual conscience, according to Hegel,

which was supposed to be the reason why, for example, the Greeks did not distinguish between individual and common interests. Freedom was still incomplete type then.

With Socrates, who took up the command of the Greek God Apollo, “Man, know thyself,” a strong force that went against the order of the Athenian state entered history. Although Socrates was sentenced to death, the principle of individual thinking remained active, and it brought about the downfall of Athens. The Roman world represents the next stage of world history, as it consisted in a collection of many different types of peoples, held together by the absolute power of the state, which represents the natural world. There was a constant tension between the natural world and the individual wills. As a consequence, human beings recognized their own spirituality, and in that way the natural world became less important and the Christian religion came about. Christianity is special because it is based on Jesus Christ, a person who is both a human being and the Son of God. He is supposed to reveal that all human beings participate in God or are made in the image of God. It is not the natural world to which humans belong, but the spiritual. This step represents the negation of the main focus of the natural world. The next step took place in the Germanic world, as there within the Reformation, it was recognized that it is not sufficient to solely concentrate on one’s spiritual life but that it is necessary for living an appropriate religious life, if one adapts the natural world to the needs of free spiritual beings.

The Enlightenment and the French Revolution with their focus on the rights of man are seen as the next and almost last step in the unfolding of freedom. The significance of the French Revolution lies in the fact that it passed on the right principles to other nations—again, Hegel had Germany particularly in mind. The idea of freedom is present only in a state in which both *subjective freedom*, which consists of the convictions of all the individuals, and *objective freedom*, which encloses laws and a rationally organized state, are realized and responsible for governing the state. Only then, the history of the world will have reached its goal. Although Hegel does not explicitly say so, it seems that Germany of his own time came pretty close to such a conception.

HEIDEGGER, MARTIN (1889–1976)

The fields of phenomenology and existential philosophy found a powerful voice in Martin Heidegger, a German philosopher best known for his concept of *Dasein*. A controversial figure who initially embraced and later repudiated Hitler and the German Nazi Party, Heidegger’s philosophical and even cultural influence remained strong until late in his life.

As a university student, Heidegger abandoned early clerical leanings in favor of mathematics and philosophy and made significant contributions in the latter field. While on the faculty at Freiburg University, Heidegger affiliated himself with Edmund Husserl, a man widely regarded as the founder of the philosophical discipline of phenomenology. Heidegger published his best-known work, *Being and Time*, in 1927, while a professor at Marburg University. In *Being and Time*, Heidegger took very strong exception to the prevailing tendency of professional philosophers of the time to focus on questions relating to theory of knowledge (epistemology). In stark contrast, Heidegger took up classical metaphysical questions from the fresh standpoint of the early 20th century. Rather than quibble about how or whether we can know this or that, Heidegger resurrected many of the deep questions that occupied the earliest philosophers. His enquires focused on the question of being and the nature of existing things in general.

Although much of Heidegger’s thought is rightly regarded as abstract, it is no less true that he sought to temper his pursuit of the larger question of *Sein* (being) with the equally significant question of *Da-sein* (“being there”). *Dasein* is a difficult word to translate and is typically rendered in English simply as “being there.” This awkward translation does not, however, even begin to capture the nuances

Heidegger intended with Dasein, which has the sense of “human existence” or, rather more broadly, “what it means to be human.”

Dasein is the central concept of Heidegger’s philosophy. So concerned was Heidegger with capturing and explaining the meaning of Dasein that his *Being and Time* begins with an analytic, or explanatory analysis, of Dasein. Among other descriptions, Heidegger characterizes Dasein as “average everydayness,” the ordinary condition of typical human existence. Dasein represents, among other things, the emergence within the individual of a conscious awareness of his presence in the world as an emerging manifestation.

In his concept of Dasein, Heidegger gives voice to the idea that “existence precedes essence.” While Jean-Paul Sartre, a French contemporary of Heidegger, would make more explicit use of this notion than did Heidegger, this idea remains in the background of Heidegger’s thinking about human existence. Although the idea that “existence precedes essence” dates back to at least the beginning of the second millennium, it figures prominently in the existential philosophies of Heidegger, Sartre, and other existentialists. As applied to existential philosophy, the notion that existence precedes essence means that there is no set “human nature” and that consequently each individual must create his or her own identity. To create one’s identity out of the bare fundamentals of the fact of one’s existence in time and place is to live authentically, to take responsibility for one’s own life and character, and to become in the end the person one has chosen to be.

HENOtheISM

In the mid-to late 19th century, the eminent linguist, Orientalist, and comparative religions scholar Max

Müller (1823–1900), one of the founders of the “scientific study of religion” (*Religionswissenschaft*) and the “father of nature mythology,” coined the term *henotheism* from the Greek words for “one” (*hen*, neuter) and “god” (*theos*). Müller had translated the Vedas from Sanskrit and had observed that a Vedic poem would praise a personification of nature in the most exalted terms—“Creator,” “Giver of Life”—as though (s)he were the only one, true god, which would be monotheism (*monos*, “one,” “only”; *theos*, “god”). However, other poems were just as laudatory in praising other gods/goddesses, which would be polytheism. Müller sought a new term for this phenomenon. His usual language was *henotheism*, literally “one god” (but not the *only* god). Occasionally, however, he also used the term *kathenotheism*, which captures the parallel idea that one god(dess) after the other was being praised (*kath’* + *hen*, “one-by-one”; *theos*, “god”).

Henotheism (*kathenotheism*) should be distinguished from *monarchial polytheism* and *monolatry*. In monarchial polytheism, Müller’s polytheism, one god becomes supremely powerful among the gods in a fixed hierarchical arrangement. Examples are Zeus in the Greek pantheon or Isis in the Egyptian pantheon. Monolatry (monolatry) describes the affirmation that only one god of those admitted to exist (polytheism) is truly efficacious and therefore worthy of *worship* (Greek *monos*, “one only”; *latreuō*, “I worship”): “Our god” is greater than “your god(s).”

Henotheism was conceived in a 19th-century European intellectual climate influenced by colonial contact with non-Western religions and the quest for the origin and evolution of religion. Ernest Renan (1823–1892) had claimed that the unique contribution of “the Semites” was monotheism and that, moreover, monotheism was the earliest form of religion. Müller countered by claiming that Renan’s theory simply echoed the medieval view that an original revelation had fallen victim to polytheistic idolatry in all the nations but the Jews. Influenced by the Romantic philosopher Schelling (1775–1854) and armed with the Vedas, Müller held that henotheism came first. As dialects evolve into a formal language, he argued, so henotheism evolves into hierarchical polytheism. The evolution continued: First came the quest for an underlying unity, either monistic pantheism (the *Upanishads*) or monotheism (the Jewish Bible), and finally, there might also appear an atheism

that leads to true faith, as in the case of the Buddha, Socrates, and “the blasphemer” Jesus.

Müller’s henotheism concept had elements from the psychology of religion. One of his definitions was the belief in and worship of objects in which humankind first suspected the presence of the invisible and infinite. These objects, Müller believed, were raised into something “more than finite, more than natural, more than conceivable.” Müller offered many examples from the Vedas to show how natural objects (for example, the sun) evoked awe and were given names, then personified, then placed in a divine family, and finally described with exalted titles.

Müller argued that henotheism also appeared among the Greeks, Romans, Germans, and Israelites. With respect to the last, descriptive phenomenologist James Livingston has recently referred to the revelation of God’s name as “Yahweh” in the Sinai theophany (Exodus 3:4–14), as follows: “It is not a fully conceived monotheism but a henotheism that, for intents and purposes, can be called ‘practical monotheism.’” Recent specialists in Israelite religion seem less inclined to use the term, perhaps reflecting the tendency to abandon the quest for origins and evolution in general. However, scholars still debate related phenomena: the Hebrew plural form of God’s name (*Elohim*); God’s image as “male and female” (Genesis 1:27); Yahweh’s connection with Canaanite gods; the divine court; and monotheism as a late (post-Exilic?) historical development.

HERACLITUS

Heraclitus was a Greek pre-Socratic philosopher, born in circa 540 in Greek colony of Ephesus, in Ionia, Asia Minor, where he is said he have spent all of his life, and died there circa 480 BC. He was known as “The Obscure” or “The Riddler,” due to his difficult, elliptical, and paradoxical style of writing. The fragments of his philosophy have survived only through citations by other classical authors in the form of some 100 proverbial sentences. By expounding the nature of things, he intended to observe the anthropological consequences for human life. Heraclitus aimed at true wisdom and moral virtue, which is based on the knowledge of nature even if not limited to it. For instance, he advised humans not to fear conflicts and opposites and regard these as normal conditions of life. In his writings, he basically claimed, in opposition to Thales, Anaximander, and Pythagoras, that everything is derived from fire, rather than from air, water, or earth. For Heraclitus, the eternal fire was not only the primary material and cosmic principle, out of which and to which all phenomena arise and return, but moreover, it was the symbol of universal and constant flux by which everything could be explained.

By Heraclitus’s flux doctrine, exemplified in his famous aphorisms *Panta Rhei*, or “Everything is in flux,” and “You cannot step into the same river twice, for fresh waters are ever flowing in upon you,” he opposed ideas such as those of Parmenides, who argued that change is an illusion and that everything is fundamentally static. Heraclitus further associated fire with god, soul, life, and intelligence. Fire is not destructive; it is a transformative force, the source of life and the light of thought and knowing.

Another of Heraclitus’s aphorisms, “All things are one,” shows that he was also in search of an ordering principle of the world. The multivalent idea of *Logos*, meaning “the word,” “the god,” “the law,” “the reason,” “the mind,” “the rule,” “the common,” and so on, served him in this respect as the cosmic uniting formula for all change, differences and opposites. *Logos* also served as the moral law for human beings. To understand the world, human beings must listen to the *Logos* of nature as well as the *Logos* within their selves. The human psyche must inquire into itself, which is one of the most difficult things, in order to become wise and cultivated. Moreover, *Logos* can

serve as the guidance for moral human action. This is the way to avoid the relativity of values and acquire genuine human dignity.

Heraclitus attacked many human prejudices, including fear of death and desire for the afterlife. According to him, human beings should consider themselves as a very unique but integral part of nature. Their uniqueness consists precisely in their intelligence, allowing them to live an examined life. Thus, Logos provides the unity of nature and the human world. Heraclitus's influence on later philosophers, such as materialists, pantheists, and dialecticians, has been substantial.

HERMENEUTICS

Hermeneutics is both the science and art of interpretation and understanding and has been applied to a broad span of disciplines and forms of scholarly inquiry. The roots of the term trace back to the Greek verb *hermeneuein*, which means “to interpret” and is found in the works of both Aristotle and Plato. However, Grondin maintains its emergence in the 17th century. Hermeneutics is commonly applied to the theological study of biblical interpretation, as well as literary theory, foundationalism, deconstruction, philosophy, politics, and a host of others.

Hermeneutics challenges (within disciplines) the historical or established meaning of an object or a given work. A work is most often seen as being man-made,

whereas an object is the craftwork of nature. Works and objects are commonly understood within the established content or framework of a scientific discipline. The disciplinary content includes both the focused theoretical perspectives and specific terms unique to that field of study. It is the creation and application of this disciplinary understanding with which hermeneutics takes issue. Hermeneutics asks, “How do we know that the traditionally applied understanding of a work or object is correct” and “How do we know that anything is correct”? These fundamental questions are asked with the realization that disciplines have established laws or methods as a formal framework that guide their analysis. These guidelines for interpretation may be inherently inappropriate for an objective examination and untainted understanding of a given work or object. This condition is attributable to their principal beliefs being grounded in myopic or flawed thinking.

The meaning of words can change from one generation to another and most certainly from one century to another. Consider how diverse the English language is and the dynamic and ever-shifting meaning of words. Imagine attempting the translation of English into Hebrew and the inability to capture the accurate meanings. Who can know the true intent of an artist's work, the motivation of a composer, or the crafters of a constitution hundreds of years old?

Hermeneutics views the historical analysis of works and objects as generally laboring under the weight of applied cultural values of its contemporary society. These values are a central component of the process of problematic interpretation. Cultural values impacting interpretation are manifest in many forms. Examples are found in numerous areas, including law, art, social fields, religion, literature, economics, and language. Often, interpretations rise to the status of accepted understanding, frequently consistent with being a certainty. Hermeneutics looks at the sciences as making interpretations and arriving at understandings by following the law of their own subject matter and taking on the position of the “purveyor of all truth.” All truth is seen as problematic when determined in the absence of a hermeneutic perspective.

The science of hermeneutics applies the philosophy of *phenomenology*, which means, according to Palmer, “letting things become manifest as they are, without forcing our own categories on them. It means a reversal of direction from that one is accustomed to. It is not we who point to things; rather, things show

themselves to us.” There are several philosophical perspectives of phenomenology; however, it can best be looked upon as a lying open of consciousness or a disclosing of being as a method of hermeneutical investigation (or also known as a “hermeneutic”). The hermeneutic requires the intersubjectivity of the investigator and for the investigator to achieve interpersonal distance from the object of study.

HERSKOVITS, MELVILLE (1895–1963)

Melville Jean Herskovits spent most of his career in the anthropology department of Northwestern University, which served as a base for research focused on West and East Africa, the Caribbean, and the United States. He began as an assistant professor at Northwestern (1927), where he soon became chair (1938), created the first department of African Studies (1951), and coaxed the library into developing one of the best African Studies collections in the world. He was born on September 10, 1895, in Bellefontaine, Ohio, and died on February 25, 1963, in Evanston, Illinois. Herskovits studied briefly to be a rabbi at Hebrew Union College in Cincinnati (1915–1918), served in the army (1918–1919), received a BA in

history from the University of Chicago (1920) and an MA in sociology (1921) and then a PhD in anthropology (1926) from Columbia. Herskovits carried out research in Dutch Guyana (now Surinam) during summers of 1928 to 1929, Trinidad (June–September 1939), Haiti (summer 1934), and Brazil (1941–1942), as well as more frequent work in Africa (West, East and South).

Herskovits became known for espousing a cultural anthropology combining cultural relativism and a theory of ethnicity rooted in cultural history derived from Boas. Herskovits countered widespread theories about African American societies being pathological (in the sense of culturally damaged and disorganized) with a detailed argument about the evidence for a rich African heritage within current African American social organization, rooted in the similar societies found between Senegal and Angola during the time of the slave trade. Herskovits maintained that both African American and African societies have evolved since this time and cannot be expected to have developed in the same way.

This argument, also espoused by W. E. B. DuBois, became popular among African Americans because it provided a basis for ethnic solidarity and an explanation, other than poverty or social collapse caused by racism and the surrounding hostile social or urban environment, for the frequency of traits such as extended-family child care, rather than exclusively nuclear-family child care on the European model. Herskovits also documented continuity in language features and kinship systems as well as slave rebellions to counter arguments that African American society had been broken by slavery.

In his dissertation, Herskovits first theorized about what he called a “cattle complex” among pastoralists, especially in East Africa. This involved a cultural set of attitudes toward cattle that involved religious and social aspects that acted to counter what Western economists would call “maximizing behavior.” The idea was not that those with the cattle complex were irrational, but rather that these cultural beliefs supported a long-term adaptation that was arguably superior to the short-term maximizing behavior economic theory would consider optimal.

Herskovits drew from numerous social sciences to make his points, but he viewed culture as learned behavior and took an ethical position (cultural relativism) that precluded ethnocentric judgments. His tendency was to minimize, though not ignore, the

influence of national or global forces on culture and emphasize endogenous development. Herskovits maintained extensive ties with African intellectuals and invited African scholars to Evanston. He was an advocate of civil rights and supported with his name and membership numerous groups that by mere virtue of their advocacy, or due to the U.S. Communist Party's infiltration, became viewed as communist front groups by the House Un-American Activities Committees. Freedom of Information Act documents indicate Herskovits was suspected of communist sympathies but regularly stated his antipathy to any form of totalitarianism and was apparently not deemed a communist by the committees or the Federal Bureau of Investigation.

HEYERDAHL, THOR (1914–2002)

Thor Heyerdahl, noted explorer and author, was born in Larvik, Norway, on October 6, 1914. After studying zoology and geography at Oslo University, he married and traveled to Polynesia. After a period of familiarization with the island way of life and culture, the Heyerdahls chose a primitive lifestyle on a remote Pacific island, Fatu Hiva, in the Marquesas group. While there doing research on the transoceanic

origins of the island's flora and fauna, Heyerdahl observed that the prevailing winds and currents came from the east, bringing with them many local plants that were unique to the American continent. As a result, Heyerdahl became convinced that because the oceans served as a natural means of transport that enabled people to move around the world, perhaps the first migrants to Polynesia might also have come from this same direction.

Scientific opinion at the time maintained that it was an impossibility for early navigators from South America to reach Polynesia. This was a theory Heyerdahl refused to accept. So, he embarked upon the construction of a primitive raft, a replica of those used by early South American Indians. Made of nine balsa wood logs from the forests of Equator and lashed together with crossbeams and covered by a deck, the *Kon-Tiki* set sail from Peru on April 18, 1947, intending to demonstrate that navigation was possible for pre-Incan peoples sailing from east to west, using the South Equatorial Current to settle Polynesia.

In contrast to European craft, the raft owed its safety and seaworthiness to its ability to rise and fall with any threatening sea and the wash-through construction, which allowed the water to drain through the logs like a sieve.

On the perilous journey, Heyerdahl and five companions, dependent on the sea and sky for their survival and with logs increasingly becoming waterlogged, made landfall 101 days later on Raroia Atoll, Tuamotu Archipelago, south of the Marquesas, after some 4,000 miles. The exploits of the voyage are recorded in *Kon-Tiki Expedition* (1948), which sold millions of copies and is documented in the film of the same name. The journey demonstrated that migration from South America to Polynesia was possible, despite much skepticism. However, currents theory and supporting evidence from archaeological, cultural, linguistic, blood-grouping, and genetic sources showed that the Pacific Islanders had made long and gradual colonization of the Pacific from the Old World.

Following the success of the *Kon-Tiki* expedition, Heyerdahl organized and led expeditions to the Galapagos Islands and experimented with Peruvian centerboards, called *guaras*, used for steering, which allowed a raft under sail to turn about and resume a new course into a contrary wind and current, as does a rudder in a European craft. This added further credibility to his claim that sustained voyages were possible to and from the South American coast.

Thor Heyerdahl continued his research on ancient navigation with expeditions to Easter Island in 1955 to 1956 and the *Ra I* expeditions of 1969 to 1970, when he devoted his energy to the ancient reed boats made of papyrus. These boats were thought to become waterlogged after less than 2 weeks on open water. With 12 tons of papyrus reeds, a 15-meter vessel was constructed and was launched from Sofi, Morocco, and sailed 2,700 miles in 56 days before foundering and being abandoned 1 week short of Barbados due to storms and deficiencies in construction. Ten months later, Heyerdahl tried the same voyage with a smaller vessel, *Ra II*, from Sofi to Barbados, showing once again the possibility of travel using ancient technologies. This gave reinforcement to his theory of linking the similarities of the Mayan and Aztec cultures to Egypt and Mesopotamia by establishing the possibility of an oceanic connection.

In 1977, Heyerdahl sailed 3,600 miles on the largest of his reed ships, *Tigris*, to suggest the possible linkage of Egypt, Mesopotamia, and the Indus Valley by open ocean, rather than long-distance camel routes.

Thor Heyerdahl died on April 18, 2002. Although evidence contradicts most of his theories, he used tools and techniques from the past and materials available to an adventurous people to expose the world to different ideas through his epic journeys.

Hinduism is arguably one of the most difficult of the major world religious traditions to accurately define and explain in any concise manner, especially using Western models and modes of understanding. Unlike the Judeo-Christian approach to religion, in which a specific text, a unique prophet or set of prophets, and the teachings attributed to these prophets establish the main parameters of the faith, Hinduism cannot be contained or defined in this way. What has come to be called “Hinduism” has had multiple influences in its origins and evolution, and it has myriad different manifestations. Yet amidst all these differences, there are certain basic concepts, beliefs, and approaches to life that, in one form or another, provide a continuum and a thread to link present to past. These will be discussed herein.

Hinduism, like most of Asian-based traditions, is difficult to understand when viewed and analyzed through Western religious paradigms. Moreover, many of the methodologies for understanding religion in the academic environment today were developed by Europeans using Christian patterns and preconceptions. Thus, while these tools may be valid for dissecting and analyzing those traditions that

Hindu offerings placed throughout a family compound guarantee the protection of everyday life.

originated in the Middle East, they are far less valid, and sometimes even distracting, when using them to look at indigenous or Asian traditions.

For many practitioners, Hinduism is not a religion in the Western sense, but more a philosophy, value system, and set of guidelines by which they lead their lives. Hinduism has no founder, no specific doctrine to which all followers must adhere, and no one leader. Membership is not dependent on faith in a specific text or prophet. For the most part, it is not viewed by its adherents as the only way everyone must live. Instead, many Hindus compare the various religious traditions to differing paths up a mountain. Each one follows a different route, but they all eventually end up at the top. This does not mean that Hindus see their tradition as no different than any other. It is that they tend to accept others and their traditions at face value and feel no need to convince them to follow the Hindu path. In fact, more orthodox Hindus feel that one must be born into the tradition.

Origins

Like all indigenous religious cultures and traditions, Hinduism arose out of the peoples and cultures of its birthplace, the land of India. Its origins are a topic of great debate and discussion by Hindus and by Western-educated scholars. While the former see the

beginnings of the tradition going back thousands and even hundreds of thousands of years, the latter theorize a much more recent origin, perhaps three to four millennia ago. What is generally agreed upon, though, is that there was a thriving civilization in the Indus Valley region (now in Pakistan) prior to the second millennium BCE. Unfortunately, our knowledge of it is limited due to a lack of any historical records. What is apparent is that there, very early in the history of the tradition, was a rich heritage of sacred chants, the earliest of which are the Vedas. These come to be viewed within the orthodox tradition as the supreme source of truth and to this day

are revered as the ultimate authority by many. Subsequent to the Vedas, yet a part of them, came the Upanishads. These texts are highly philosophical and address the nature of human existence, its relationship to divinity, and ultimate reality. The Puranas, another class of texts, focus on the origins of the universe, of the *devis* and *devatas* (female and male divinities), and of humans. They are the major literary source for Hindus' understanding of their history and their rich mythological tradition. The two ancient Epics, the *Ramayana* and the *Mahabharata*, are integral in the understanding and devotion to the two major forms of the divine in Hinduism, Ram and Krishna, respectively.

By the time Alexander the Great invaded India and the late fourth century BCE, the various elements of the developing religious tradition of India were both rich and diverse. Jainism and Buddhism were coming into form, although more as aspects of a broader tradition than as separate religions. Yet there was a thread of common beliefs and practices that connected most of the diverse streams. These commonalities have continued up to present day. They include a belief in transmigration of the soul, the concept of karma, the importance of nonviolence, the central role of the guru/disciple relationship and of religious practice, and acceptance of religious and philosophical diversity. In the last two millennia, there have been

myriad philosophers, teachers, and movements within the tradition, as well as invaders from the West. All these have added to the fabric of what Hinduism is today.

The Theory and Practice of Hinduism

Western religious traditions, especially Christianity and Islam, place a central focus on belief, both in the uniqueness and supremacy of their respective traditions, prophets, and scriptures, which they typically promote as being absolute, unique, and inerrant. In the case of Hinduism, however, there is no one prophet or one sacred text. Instead, there are many of both, and each Hindu is relatively free to pick the text or teacher he or she wishes to follow. With regard to texts, Hindus generally give perfunctory deference to the Vedas, although most actually know little as to their content and have never read any parts of them. Instead, the sacred stories found in the *Ramayana* (in its various tellings), the *Mahabharata*, the *Bhagavad Gita*, and in the multiple Puranas have been the primary written sources that have provided the vast majority of Hindus their understanding of their tradition, its beliefs, and its practices. However, more important than texts as sources of knowledge and practices for Hindus have been local traditions, the teachings of wandering *sadhus* (commonly translated as “ascetics” or “holy men”) and storytellers, and the words of one’s personal guru, or religious teacher. Thus, the way a Hindu typically understands and practices the religion is much more based on these sources than on any text or doctrine.

As a consequence of the enumerable written sources and the many teachings from wandering *sadhus* and gurus, Hinduism has a philosophical diversity, eclecticism, and tendency toward tolerance not found in other major religious traditions. Broadly speaking, each individual’s understanding and practice of Hinduism is grounded in his or her guru’s specific interpretation of the tradition, with an emphasis on practice over belief. Orthopraxy is stressed over orthodoxy. Moreover, a central focus of Hinduism is on what one does more than what one believes. It is the various religious practices (collectively known as *sadhana*) that define the religion for many of its adherents, far more than specific beliefs. For the faithful, to be a Hindu means to live the tradition by doing the practices associated with it. These can involve material things such as what one does or does not eat or wear; it can involve external practices, such as

devotional singing and chanting, doing rituals at home or at a temple, or going on a pilgrimage; or it can involve one’s internal practices, such as meditation or prayer. Any or all of these can define what the practice of Hinduism is for its devotees.

Rituals, both personal and collective, make up an important part of the practice of Hinduism. It is not so much that a particular ritual is so important or even that a particular way is important, but what is most important is that one does rituals. This is because, for the most part, rituals are believed to have the power to effectuate an elevated state of religious or spiritual purity and consciousness, and they may grant power as well.

It would be virtually impossible to record all the diverse beliefs and practices found under the name Hinduism. There are hundreds of diverse ethnic and linguistic groups, hundreds of different caste groups, and thousands of different religious denominations and belief systems. While most of these share some common beliefs and practices, each also has its own peculiarities and unique elements. The Vedic and Tantric traditions have been the primary sources for many of the more popular orthodox rituals, especially the *agnihotra*, or fire ritual, but also various forms of chanting, fasting, and so on. The group of texts known as the Upanishads is the primary repository for many of the more popular Hindu theological and philosophical beliefs. Although there is a wide diversity of views expressed in these texts, they have several concepts in common, such as the unity of the divine, the inseparable connection between the individual soul (*atman*) and the Supreme Transcendent (*Brahman*), the importance of truth, wisdom, right action, reincarnation, and so forth. The Epics and Puranas and various devotional texts are important sources for popular beliefs, both mythological and doctrinal. These texts have also given rise to many rituals and practices as well. The following sections will be a discussion of some of the beliefs, rituals, and practices most commonly found in Hinduism, both in India and in the Hindu Diaspora.

Beliefs

The Divine

Hinduism is generally called a polytheistic religion by outsiders to the traditions. However, it is more rightly considered panentheistic, a belief in which all existence is subsumed in God, but is also transcended

by God at the same time. In short, all is in God, but God is beyond all. Added to this is the belief that God is also omnipotent and omniscient. This being the case, Hindus then see all existence, all knowledge, and all power as, on one level, divine. However, because the totality of this Absolute Divinity is beyond human conception, it takes multiple forms through which it makes itself knowable and available to humans. These forms are known as *devis* and *devatas*. Although the terms are usually translated as “goddesses” and “gods,” they should not be confused with these Western theological concepts. A *devi* is a manifestation of the Absolute’s feminine energy, power, and divinity, formed to fulfill a particular function or serve as an expression of a particular quality. Likewise, a *devata* is a masculine expression of the Absolute. Therefore, because all the *devis* and *devatas* are aspects of the One, Hindus may pray to or worship many different ones simultaneously, while still seeing them all as none other than the expression of the One Absolute. Last, because of the omnipresent view of the divine, all aspects of nature are seen to contain divinity as well, including plants, animals, and rocks.

Most Hindus actually tend to focus on one or several related manifestations in their daily worship. They may actually believe a particular one as the ultimate manifestation of the Absolute, while also acknowledging other manifestations as being divine and praying to them as well. It is also for this reason that Hindus can easily attend religious services of other faiths, such as Christianity or Islam. After all, the divine being worshipped in those religions must either be the One or a manifestation of it. Thus, while Hinduism appears as polytheistic to outsiders, it is not so either in the ultimate Hindu vision, in the complexity of the tradition’s theological views, or in the minds of its practitioners.

Brahman/Atman

Upanishadic philosophy is the primary source for understanding the concept of the Transcendent Absolute, as mentioned above. It is said to be undescrivable, unknowable, and imperceptible, and it is the source and reality of all that exists, both visible and invisible. It is called *Brahman*. It is not only that which becomes manifest as the *devis* and *devatas*, but it is also the life force in each living being, called *atman*. Atman is qualitatively, but not quantitatively, equal to *Brahman*, the relationship between the two being somewhat like that of drop of ocean to the

ocean, separate yet not separate, of the same essence but not the same. One’s true reality is *atman*, as is the reality of all living beings, and because of the intimate relationship between *atman* and *Brahman*, all beings are connected as well. With this belief, then, nonviolence, truth, compassion, and tolerance all follow naturally. The *Brahman/atman* concept is foundational to much of what is believed and practiced within Hinduism.

Karma

There are various approaches to the law of *karma*. In the Jain tradition, *karma* is the product of the interaction of soul (*jiva*), which is the life force in all visible and invisible creation and nonsoul (*ajiva*), which includes time, space, matter, and inertia. Every action, then, results in the production of *karma*, of which there are 148 different types. Those types that are particularly bad and lead to suffering and low rebirths include killing, violence, cheating, stealing, lying, and so forth. Other forms of *karma* can be uplifting, such as nonviolence, compassion, truth telling, charity, and so on. Although the latter help offset the former, the goal is to stop all karmic production in order to be liberated. The Buddhist concept of *karma* is somewhat similar, except that there is much more of a focus on intention over action. Selfless actions rid one of bad *karma* but do not necessarily create more karma. Thus, nonattachment is the vehicle to liberation, for which a teacher is important to point the way. It is this concept of *karma* that for the most part reflects the common Hindu view.

Ahimsa (Nonviolence)

The worst *karma* in Jain, Buddhist, and Hindu traditions is the consequence of murder and violence. It is believed to weigh down the soul and lead it to rebirth in a hell realm, a realm of evil spirits, as an animal or possibly as a tortured human. The corollary to this, then, is nonviolence (*Ahimsa*), which elevates the soul, rids it of bad *karma*, and furthers its progress along the path to liberation.

Punarjanam (Rebirth)

Both Jains and Hindus believe in a soul and in rebirth (*Punarjanam*). Just as a student must go through a variety of courses and grades in order to gain the knowledge necessary for graduation, so the soul (*atma*) must go through a variety of births in

order to learn all the lessons necessary for liberation. If a student fails to pass a course, he or she must retake it. In the same way, an individual who fails to learn certain lessons in a particular life must then reexperience them in a subsequent one. Both traditions, along with Buddhism, believe that liberation is an inevitable and ultimate goal, even though they disagree somewhat on what liberation actually is.

Guru/Disciple Relationship

The relationship between the teacher and the disciple has been one of the most enduring aspects of Hinduism since its roots in ancient history. Teachers, or *gurus*, have been the primary vehicle through whom Hindus have learned their religious culture. The purpose of a teacher is to instruct the student on the path to liberation. Ideally, a *guru* is someone who has already traversed the path and thus knows the way, with all its pitfalls, signs, and curves. Because one's *guru* is said to have the ability to guide each disciple on his or her path to the divine, the *guru* is to be treated with highest respect. More than a scripture, a particular school of thought, a sect, or a doctrine, the teachings of one's *guru* are to be followed as truth. The role of the *guru* has earned such a high degree of importance within Hinduism that devotion to one's *guru* has come to be seen as integral with devotion to God. While the orthodox tradition suggests only a Brahmin (a member of the priestly caste) as being qualified to be a *guru*, the reality is that most village Hindus learn more about the traditions and practices from wandering *sadhus*, many of whom are not Brahmins. Thus, the Hindu renunciant is a pivotal figure in the perpetuation of the tradition.

Dharma

There is no single English word with which to translate *dharma*, no term to describe its complete meaning, which includes belief, moral duty, righteousness, justice, virtue, cosmic law, and harmony. *Dharma* compels humans to act in a manner in accordance with the virtues just mentioned so that their actions move them in the direction of enlightenment. Thus, it is the vehicle through which liberation is gained. Mahatma Gandhi considered both truth and nonviolence as the highest expressions of *dharma*. In contemporary times, it is also used in place of the English term *religion*. The term is used in all the religious traditions that are indigenous

to India, including Jainism, Buddhism, and Sikhism. However, in each one it has a slightly different meaning.

Bhakti (Devotion)

The term *bhakti* is used in reference to several aspects of the Hindu tradition. On one level, it simply means "devotion" or "love" and as such refers both to emotional feelings of love and respect toward a particular form of the divine as well as to any of a number of practices that one might do as a consequence of such feelings. It is the primary focus of the practice of Hinduism today. As mentioned above, because Hindus believe that the Absolute Brahman is unknowable, the focus of devotion and worship is generally on its manifestations. The most common of the many *devis* and *devtas* are in the form of male/female couples, which include Ram and Sita, Krishna and Radha, Shiva and Parvati, Vishnu and Lakshmi. Each couple is seen either as dual expression of the Absolute or as the supreme expressions, depending upon the focus of one's *bhakti*. Thus, Hindus can simultaneously express devotion to multiple forms as well as to the One. Since *bhakti* is fundamental in contemporary Hinduism, Hanuman, usually depicted in the form of a monkey, is one of the most popular divinities. He is an incarnation of Shiva, the servant of Ram, and the highest manifestation of devotion, humility, and selfless service. Devotion to him, then, brings together various manifestations into one. For most Hindus, *bhakti* defines their practice of their tradition.

Caste System

Easily, the most controversial aspect of the Hindu tradition is the caste system. It is the ancient social and religious hierarchical stratification of Hindu society that has persisted up to present times. It is defended as a religious expression of one's progression toward liberation or as a formalized division of labor. It is condemned as systematized oppression and racism.

Devotional Rituals and Practices

It is virtually impossible to list all the different beliefs and practices that are connected with devotional Hinduism. However, there are several that tend to be

prevalent in most regions of India and have come to represent the general core of beliefs and practices. One category includes specific ritual practices done either at home or in a temple, such as sacred name chanting (*nam jap* or *nam smaran*), devotional singing (*kirtan*), and image worship (*murti puja*). Another category includes lifestyle practices, such as vegetarianism, nonviolence, abstinence from intoxicants, and charity.

Rituals found in contemporary Hinduism combine elements of indigenous, Brahmanical, and Tantric aspects and tend to be focused on a particular deity, although devotion to one or more associated deities is generally included. There are various ways to categorize the different types of rituals, such as who is actually performing the ritual, what it involves, what is its purpose, and where it is taking place.

Mediated Rituals

This category of rituals involves those done by any of several types of individuals for the benefit of another. Brahmin priests (or someone recognized by a community to serve as one) are the major ritual officiants. All rites of passage and many periodic rituals are traditionally overseen and performed by priests. In some areas, shamans exist as well and are often called upon to mediate specific types of rituals, especially dealing with sickness, possession, and other instances needing intercession with the spirit world. While most *sadhus*, or renunciants, do not generally perform mediated rituals, some do, especially for their immediate disciples.

One element often found in mediated rituals, especially those performed by priests, is the fire sacrifice, commonly known as *yagya* (or *yajña*), *homa*, or *havan*. This practice is one of the earliest known Aryan rituals that has survived up to present day. The central element of the ritual is the fire itself, *agni*. Originally seen as a mediator between the divine and human worlds, Agni came to be viewed as a deity himself, while the priest now acts more as the mediator. The ritual involves the offering of various combinations of foodstuffs (including black sesame seeds, grains, nuts, dried fruit, clarified butter, and so on) into a sacred fire made of sandalwood, wood from the mango tree, or other woods considered sacred. A *havan* is generally a smaller fire sacrifice with only one priest in attendance, while a *yagya* often has more and can have as many as 108. When a *yagya* is performed, it is usually followed by a *bhandara*,

which involves a feast for those in attendance and/or the poor.

Personal Rituals

These are rituals done by individuals for their own or their immediate family's benefit. In most Hindu homes, there is an altar of some sort, where women perform daily rituals. These may be as simple as lighting a candle or piece of incense in conjunction with a small prayer, or they may be elaborate observances, involving the bathing and worship of an image, incense, food offerings, and meditation. At the same time, men, unless they are a priest, shaman, or *sadhu*, tend to do rituals less often, and then usually only for themselves. Among the various elements one might find in personal rituals are prayer, image worship, name recitation (*jap*), chanting, scriptural recitation, breath control practices, and meditation.

Chanting and Jap

Traditionally, most Hindu chants have come from Sanskrit sacred texts, as Sanskrit is said to be the language of the gods, thereby possessing great power. Even though only a minuscule number of the population has ever understood the language, this fact has mattered little: The gods understand it, and that is what is important. Chants usually involve invocation of a deity, through praise, supplication, or requesting forgiveness. In more recent times, non-Sanskrit chants have also become an integral part of Hindu practice. *Jap* refers specifically to either murmured or silent repetition of a particular mantra, sacred name, or collection of sacred names. *Nam jap*, or name repetition, is one of the most common forms of religious practice for Hindus today.

Prayer and Kirtan

Unlike chants, most prayers are understood by their speakers and are usually in the speaker's native language. If a prayer happens to be in Sanskrit, the person reciting it likely knows what it generally means, if not its exact translation. Prayers can be and are recited at any time of day, in any situation, as is the case in all religious traditions. They can be internal and personal, or they can be spoken or sung aloud, alone, or with a group of persons. When done with a group, there may be some sort of musical accompaniment as well. Such activities are called *kirtan* or *bhajan* and comprise a major element of the practice of Hinduism.

Yoga

Yoga is arguably of the earliest religious practices known in the Indian subcontinent. The eight-limbed system has long been primarily practiced by renunciants and has never been commonplace among the lay population. Its traditional purpose is to attune the body and focus the mind to assist on the path to enlightenment. However, in more recent times, yogic practice has become a popular activity in urban areas of the West, primarily for the purpose of keeping physically fit. As a consequence, its popularity in urban India is also increasing.

Vrat (Fasting)

The taking of a restrictive vow, or *vrata*, is an important religious undertaking for a Hindu. This can involve any form of sensual-pleasure restriction, and a food restriction fast is the most common. Many Hindus include some sort of dietary *vrata* on a regular basis, such as vegetarianism, a weekly fast (such as on Tuesdays for Hanuman or Fridays for the goddess), or a several-day fast once a year. The actual type and length of fast is to be self-determined. For renunciants, undertaking *vrats* is integral to that way of life.

Sacred Texts

Reading or chanting from sacred texts has increasingly become a popular form of Hindu religious practice, and of all the major religious traditions of the world, none has the diversity of sacred texts as does Hinduism. Starting with the Vedas, the number of texts that have been written and are viewed as sacred, by one group or another, is vast. Although formal deference is generally given to the orthodox texts, the Vedas and Upanishads, the vast majority of Hindus neither read them nor know much about them. Instead, devotional writings are the scriptural focus of Hinduism today. In north India, the primary sacred text is the *Ramcharitmanas*, a 16th-century telling of the Ramayana story by Tulsidas in a dialect of Hindi. It is regularly read, chanted, memorized, and recited in homes and gatherings throughout north India. It was also made into a serialized television program in the early 1990s, and whenever it was being shown, urban India almost came to a standstill. For Krishna devotees, the *Bhagavad Gita*, the *Mahabharata*, and the *Bhagvata Purana* are the most popular texts. In south India, the *Periya Puranam* both inspires and reflects the devotion to Shiva in the hearts of the populace.

Diaspora Hinduism

Starting in the 1830s, the British government began shipping thousands of impoverished Hindus to British-owned plantations around the world to work as indentured servants. By the time the practice ended, more than a million Hindus had been sent to Fiji, the Caribbean, Mauritius, and South Africa. In the process, the Hindu Diaspora was born. Although the indentured servants were primarily rural, illiterate, and poor, and missionaries in these lands worked hard to convert them to Christianity, their faith in their Hindu traditions persisted, and today Hinduism is thriving in these lands. Moreover, many Diaspora Hindus have become important spokespersons for international Hinduism. Diaspora Hindus have also migrated to Western Europe, Canada, and the United States, taking with them a form of Hinduism that also reflects the Diasporic experiences and cultures.

The Diaspora religious practices mirror many of the practices in India, especially *bhakti*, and the *Ramcharitmanas* is likewise the most popular scripture. Unlike the Hinduism of India, however, there is essentially no caste system in Diaspora Hinduism, since the indentured servants wisely chose to reject the system in their new lands. The consequence is that Diaspora Hindus have also become important figures in the fight to remove the prejudice of the caste system from the practice of Hinduism altogether.

HISTORICISM

Historicism is a theory of discerning the past truth from the study of history with man at the pivot. It was applied by 18th-century philosophers of Enlightenment and gained momentum since then, with the insistence that history is knowledge. It is the implication of the knowledge of history in explaining, besides history, a vast range of traditional subjects, like theology, philosophy, art, and literature. *Historicism* is a sort of tag attached to different disciplines, meaning things in the said discipline can be explained and understood by the knowledge of history. Previously, it was believed that such knowledge is apocalyptic. In history, it is applicable to Darwinian interpretation of social evolution and Marxist interpretation of dialectic materialism.

Broadly, the theory of historicism means that man may learn from history something the great religions believed that they learned from revelation. The application and value of history increased a hundredfold by this theory. As such, this is a theory of historical inevitability, a sort of historical determinism. It is the science of answering questions through historical records and repudiates the early belief of God guiding the steps of human beings (apocalypse). On the contrary, it theorized the materialistic view of the universe, insisting that man himself made certain laws through experiments and systematic observations that guided his steps, giving meaning to human life. Man is constantly thriving to derive and explain these laws. The scientific methodology of history as a collection of a mass of data together with constantly increasing ability to classify and analyze those data—encompassing facts related to socioeconomic changes, the beginning and growth of institutions, lands, and the people bearing upon individual and mass psychology—have made the task easy.

The historians have discovered uniform tendencies governing movements of religious enthusiasms. They are the same for the rise of Christianity, Islam, and Buddhism. Also, the same is applicable for the rise of nationalism in Europe, America, and Asia. This implies that there are certain laws through which historical events occur and can be explained.

Historicism derives its roots from the law of change, which proclaims that what existed in the past would not exist today—and in the same manner, what exists today would not exist tomorrow. One

should think historically about this law of change, and a historian should not accept the verdict of past authors without criticism. Historicism claims that there can be a preimagination of social future on the basis of historical understanding of the law of change. The German philosophers, however, conceived of the term *historicism* differently. Dilthey, being influenced by the 17th-century religious mysticism, believed in the historical concept of the solidarity of human race and its inevitable progress through an inner strength. He is the theoretician of that moderate spirituality that escaped positivism and thus, in turn, generated the so-called crisis of historicism.

For Ernest Troeltsch, historicism was the radical historicization of our knowledge and thought. All objects are determined by the past and are directed toward an unknown future; hence, state, law, art, and all others are dissolved in the stream of history intelligible to us as constituent parts of historical development. Troeltsch considered naturalism and historicism as the two great scientific creations of the modern world, conceiving them as homologous and juxtaposed. Though he was against the idea of unlimited historicism, he perceived it as an absolute universal and extrahistorical truth, which was the presupposition of any historiography (the conquest of historicism).

Friedrich Meinecke referred to historicism as the sense of the value of individual and individuality of nations that had been derived from the 18th-century European secular standpoint, from which the Germans had investigated the essence of individualism (cosmopolitanism and the national state), and traced the history of the 18th-century thought (the origin of historicism). Benedetto Croce used the term *historicism* to mean freedom of historical thought by rigidly defining the competence of each and showing that none had the right to usurp the place of historical thought. He insisted that historical attitude does not have to justify the object of its knowledge through other thoughts, but that historical thought stands both at the base and at the summit of all genuine truth. Hegel and Karl Marx used the term *historicism* to explain the historical philosophy of determinism. Hegel used it to explain “knowledge”: the concept of social science that can derive and produce knowledge from the study of past for the benefit of society. For Hegel, it was a historical philosophy of “knowledge.” M. C. D’Arcy used the word *historicism* as being identical with a philosophy of history.

Historicism thus became a term of multiple meanings. In the 19th and 20th centuries, it became all the

more important, because as a consequence of this school of thought, people were convinced that they understood where the forces of history were leading and that they could further help and hasten the process, thus gaining a mastery over the secrets of universe. Historicism is not just knowledge, but the science of making predictions with the knowledge of history. It leads to positivism in interpretation.

With the publication of *Poverty of Historicism* (1957), by Karl Popper, the theory came into vogue, creating a wild storm of heated discussions in the mid-20th century. In the introduction, he described historicism as “an approach to the social science which assumes that historical predictions is its principal aim.” Popper thus made use of the term to mean a method of approach solely aiming at predicting the future course of history. It is unfortunate that he chose the term *historicism* to denote an intellectual frame that is only a species of the genus and may take many forms and could not understand what the German philosophers meant by it in totality.

In *Poverty of Historicism*, Popper discredited historicism, arguing that a constant growth of knowledge keeps influencing the human history and it is therefore impossible to anticipate the future and make predictions with any amount of certainty as in science. He gave an inventory of arguments against the scientific character and capacity of history, such as the complex nature of the subject, insufficient causal explanation, lack of quantification and experimentation, and an unavoidable selectivity of presentation. He utterly rejected the possibility of a theoretical history ruled by any laws. Furthermore, in *Logic of Scientific Enquiry*, he has stated that his theory of explanation in science can be generalized to include historical explanation. Historicism as used by Karl Popper is a doctrine that assimilates history to science and is also a doctrine sharply different from science: This is highly ambiguous and baffling.

HIV/AIDS

Human immunodeficiency virus (HIV) is the retrovirus responsible for the clinical spectrum of the acquired immunodeficiency syndrome (AIDS). Once infected by the virus, an individual is said to be *HIV-positive*. HIV then attacks and progressively destroys key elements of the immune system, rendering victims susceptible to a host of opportunistic infections and rare cancers. The development of one or more of these characteristic illnesses is what defines AIDS. “HIV/AIDS” is used to refer to the entire spectrum of disease progression from onset of infection through the advanced stages of illness.

The emergence of HIV/AIDS grew into the first worldwide epidemic since the influenza outbreak of 1918 to 1919. Unlike influenza, which struck more or less uniformly, the epidemiology of HIV/AIDS has been remarkably varied and dependent on a complex array of sociocultural elements. Politics, poverty, sexual behavior, science, and gender all conspire to produce measurable disease effects on individuals, communities, and nations. The holistic perspective of contemporary anthropology is central to understanding and managing the enormous impact of this global pandemic.

Biology of HIV

The Virus

There are two primary subtypes of HIV, designated HIV-1 and HIV-2. HIV-1 is the predominant form worldwide, while HIV-2 is limited mostly to West Africa. Both belong to a broader family of retroviruses and contain two identical RNA strands as their genetic material. A unique enzyme, reverse transcriptase, allows retroviral RNA to be copied to DNA that then integrates within a host cell. The genomic organization of HIV is similar to other retroviruses

but also has a striking predilection for genomic variability that contributes to diversity in phenotype and cell tropism. This genomic mutability is a major obstacle to the development of vaccines and effective antiviral therapies.

Infection and Life Cycle

The surface protein coat of HIV preferentially binds with a subset of circulating immune system cells known as T cells. T cells are essential for immunosurveillance and disease control, with a variety of important functions. Both T cells and macrophages (as well as some other cell populations) contain a high-affinity HIV receptor called the CD4 antigen. Once inside a host cell, HIV replication begins, and vast numbers of new particles are released, killing the host cell in the process. Newly created particles bind and infect other CD4 cells.

Clinical Phases

Acute infection is sometimes marked by “flu-like” symptoms known as the acute retroviral syndrome. Symptoms are often unrecognized by the victim or by health care professionals. The viral load is initially high, and people in this stage are capable of transmitting the virus to others. Antibodies are made to HIV but take weeks to months to develop. This interval between the onset of infection and the rise of measurable antibodies is referred to as the “window period,” a clinically important time where seronegative individuals can be infectious. The antibodies are usually detectable within 3 to 6 months.

As the immune defenses activate against HIV, a balance is struck between virus and host, but inexorably, the virus eliminates immune cells faster than they are replaced. The process can take several years. During this time, an infected individual is usually asymptomatic and can unknowingly spread the virus. A gradual fall in CD4 cells accurately reflects disease progression. CD4 counts normally range from 1,200 to 1,400 cells/mL. When HIV reduces those numbers to around 200/mL, opportunistic illnesses begin to appear and the person is said to have AIDS. In the absence of treatment, the prognosis from the onset of an AIDS-defining illness (or a CD4 count less than 200) to death is usually 2 to 24 months.

Transmission

Science has documented only three established modes of HIV transmission: (1) sexual intercourse

with an infected partner, either via heterosexual or homosexual contact; (2) parenteral (blood-borne) exposure to contaminated blood, usually via transfusions or intravenous drug use; (3) perinatal spread from infected mother to fetus, either in utero or at birth or through breast-feeding. Within each of these modalities, there is a wide range of infectivity rates, depending on host, viral, and environmental factors. Interventions directed toward these exposures form the medical basis for most HIV control programs. Anthropologic research, however, further asks what political, economic, or behavioral factors exist to influence people’s willingness to accept such interventions.

Diagnosis, Treatment, Vaccines

Confirmation of HIV infection is made through a variety of laboratory testing methods. Samples are usually taken from blood but can also be taken from saliva or urine. Standard ELISA and western blot methods detect HIV antibodies but are usually not sensitive enough to detect early infection in the window period. When clinical suspicion is high, a viral-load assay using polymerase chain reaction (PCR) technology can identify an acute infection before antibodies are measurable. Although all the tests are very accurate, a thorough understanding of the natural history of HIV infection is crucial for correct test interpretation and awareness of various diagnostic pitfalls.

Once HIV is confirmed, testing can be done to determine the virus subtype and/or its genotypic resistance to antiviral drugs. Some of these measures, such as the quantitative viral load and CD4 counts, help predict a person’s survival time as well as his or her risk of an AIDS-defining illness.

From an anthropologic perspective, the treatment of HIV/AIDS involves a holistic approach that addresses the socioeconomic context of the individual and not merely the medical aspects. Recent advances in antiretroviral drug therapy, for example, have greatly improved survival times but raised a host of ethical questions regarding access, cost, monitoring, and research protocols. Pharmacologic therapies against HIV started with azidothymidine (AZT) in 1997 and have expanded to include over 20 agents currently licensed by the U.S. Food and Drug Administration, available in an array of combinations. While these agents have proved remarkably successful, results are tempered by the cost (up to \$20,000/yr), the potential for multiple side effects and drug interactions, and complicated dosing regimens.

This increasing complexity has also meant that fewer health care providers are equipped with the necessary expertise and access to the best HIV/AIDS care, and thus treatment has been further restricted, with wide-ranging consequences.

In contrast to the success of the antiretroviral drugs, HIV vaccine development has yielded numerous biologic insights but no practical results. As an alternative, there has been success in some trials of antiretroviral prophylaxis, especially in the area of perinatal exposure. Prophylaxis has reduced the maternal-to-child transmission to less than 2% in developed countries, where mothers generally have access to medications and C-section expertise. The success rate is substantially reduced, however, in the developing world, where such infrastructure does not exist.

History of the Pandemic

The first cases of AIDS were reported in June 1981 by the U.S. Center for Disease Control (CDC). Physicians identified unexplained clusters of pneumocystis carinii pneumonia (PCP) and Kaposi's sarcoma, two rare illnesses known to be associated with immunodeficiency from other causes. The outbreaks occurred in homosexual men and were described initially as "GRID," or gay-related immunodeficiency disease. Subsequent investigations led to the discovery of a similar disease pattern in other groups, such as hemophiliacs and IV drug users, and the name was modified to acquired immunodeficiency syndrome, or AIDS.

Within 2 years, laboratories had isolated the HIV virus, and by 1985, the first serologic tests became available. Doctors could now establish HIV infection in patients without AIDS and effectively screen the supply of blood bank products.

HIV is currently thought to have evolved from the simian immunodeficiency virus (SIV) and is estimated to have first appeared in humans in the early 20th century. HIV-2 has proven to be less virulent than HIV-1 and remains confined largely to West Africa and India.

The current burden of HIV/AIDS is indeed staggering. 2004 data from the Joint United Nations Programme on HIV/AIDS (UNAIDS) estimated the global number of infections at 39 million. Over 20 million have already died, including 3.1 million in 2004. The seroprevalence among the living ranges

from 0.2% in Oceania to 7% to 8% across sub-Saharan Africa. Many local communities have much higher prevalence rates. Around the world, the number of people with HIV continues to rise in every geographic region, including sharp increases in China, Eastern Europe, and parts of Asia. Women now represent 57% of adults with HIV in sub-Saharan Africa and 25% of the cases in the developed world. The increasing numbers of infected women implies an increase in perinatal acquisition.

Life expectancy has dropped by up to 15 years in some countries within Africa and the Caribbean. The number of AIDS orphans is estimated at 15 million. Despite the original description as a disease of homosexual men, 80% of global infections are now acquired heterosexually. Epidemics in Eastern Europe appear to be driven by increasing intravenous (IV) drug use, which also fuels epidemics in some areas of China and East Asia. The future of HIV/AIDS remains uncertain, given the mutability of the virus, the current limits of therapy, and the uneven application of control efforts to the culturally diverse populations of the world.

Anthropologic Perspectives

Anthropologic research methods, with their historical depth and engagement in society, culture, and evolution, have an almost limitless relevance to the global complexities of HIV/AIDS.

At the core, anthropology asks: Given our biological knowledge and the availability of effective medical and behavioral solutions, why does HIV continue to spread? What impacts does this have on human populations? These questions can be addressed in the context of individual behavior, moving to various risk groups, and ultimately to whole communities or regions. Clinical anthropologic subfields have been at work at each level.

Biological Anthropology

Biological anthropologists focus on the relationships between human biology and culture or disease spread. This approach has been especially important in examining the variables of HIV infectivity within different population groups. For example, within the three known modes of HIV transmission, infectivity rates vary widely. The risk of transmission from a contaminated needle stick injury is limited to less

than 1%, while the risk of transmission from transfusion of infected blood products approaches 100%. Infectivity rates among IV drug users fluctuates in between. Likewise, the risk from receptive anal intercourse is higher than for other types of sexual transmission, and the presence of concomitant sexually transmitted diseases (STDs) (especially ulcerative genital diseases) is associated with yet higher risk. Mathematical and epidemiologic models have been used to evaluate these variables with a host of other factors, including number of exposures, the probability of encountering an infected partner, and the mutability and virulence of HIV strains. Physical anthropologists also address the coevolution of HIV in both human and other primate hosts.

Linguistic Anthropology

Linguistic anthropologists study the usage and meaning of language, both within and across cultures. Language studies have helped evaluate the way HIV and illness are perceived and acted upon, from isolated Asian hill tribes to urban gay men. One UNAIDS scholar has recently addressed the imperative for integrating indigenous African cultures to Western technological discourse through an effective “language policy.” Such a policy would allow modern ideas about HIV/AIDS to be better incorporated at the local level. The problem was contrasted with Asian countries, such as Japan and Singapore, where indigenous language and culture have been preserved while still absorbing the language of modern science.

Symbols such as the AIDS quilt have been studied to better understand societal mechanisms of grief and remembrance.

Cultural Anthropology

Methodologies from cultural anthropology have had tremendous influence on our understanding of HIV. The basic health belief model, developed in the 1950s, has been employed in various forms to obtain information about an individual’s perceived susceptibility, severity, benefits, and barriers regarding any threat to health. Standard ethnographies provided a framework for understanding which practices exist in a given culture that could contribute to disease spread, such as the Masai practice of brothers who take in widowed sisters-in-law. KABP surveys (Knowledge, Attitudes, Beliefs, Practices) have been widely applied to obtain data sets from which to analyze behaviors. These techniques helped identify such

causal associations as the use of recreational drugs and heightened HIV transmission among gay men, as well as the ways in which HIV misinformation propagates stigma and discrimination by health care workers toward AIDS patients. Many of these surveys have emphasized how even sound practical knowledge of HIV and its effects has failed to translate to meaningful behavior change.

The development of rapid anthropologic assessment techniques, largely qualitative, has improved the acquisition of cost-effective comparative data that help govern priorities in many aid programs.

Anthropology and Policy

As if the challenges of data acquisition and interpretation were not enough, there remains the essential work of translating social knowledge and theory about HIV into political action. Social scientists of all brands have been consumed with the monumental tasks of advising governments, negotiating goals, and assessing results. The immediacy of the human suffering has given rise to AIDS activism and thereby also exposed the face of AIDS apathy. One of the most dramatic examples of political controversy has played out in South Africa, where government leaders actively resisted organization of a national antiretroviral treatment program until 2003. Their concerns were based partly on skepticism about Western-generated HIV information and the racist implications. South Africa’s president publicly questioned the profit motives of giant pharmaceutical companies. As the debate escalated with data from both within and outside the country, public policy slowly shifted to embrace antiretrovirals. Worldwide pressures also helped convince drug makers to lower prices and thus improve access in both rich and poor nations. Currently, however, only 4% to 5% of HIV patients in the developing world even have access to antiretroviral regimens, so the mandate to address this gap will require both political will and the necessary funding. Of course, political structures themselves will necessarily change, as HIV/AIDS continues to affect demographics and economics by claiming younger men and women, who traditionally make up the healthy skilled workforce.

HOAXES IN ANTHROPOLOGY

Virtually all fields of science are afflicted to some extent by hoaxes. Anthropology is no different, with each of its subfields having been subjected to at least a measure of intellectual dishonesty and fakery. Though the motives behind anthropological hoaxes have varied, the element underlying their success has always been the same: an audience predisposed to believe the implications of the fabricated data. There is, perhaps, no better example of this than the most notorious hoax in paleoanthropology—and, perhaps, in all of science—Piltdown Man.

**Hoaxes in Biological
Anthropology: Piltdown Man**

The world first heard of the discovery of human fossil remains at Piltdown in a short announcement published in the British science weekly *Nature*. On December 5, 1912, that publication reported the discovery by Charles Dawson, a lawyer by trade but a collector of scientific specimens by avocation, of

fragments of a human cranium and mandible in Sussex, in the south of England. The remains appeared to be greatly ancient, having been recovered from a stratigraphic layer in which the bones of extinct animals had already been found. A follow-up article in the same journal two weeks later provided sufficient detail to grab the attention of both the scientific community and the world at large.

The discovery of ancient human remains has long been newsworthy, but the initial and subsequent published descriptions of the bones found at Barcombe Mills Manor, in the Piltdown region of Sussex, indicated that they were more than simply newsworthy, they were revolutionary. The bones were perceived to be extraordinarily important precisely because they were so different from ancestral human remains discovered previously. Consisting of several humanlike cranial fragments and part of an apelike mandible, the fossils were given a new taxonomic name reflecting their unique characteristics: *Eoanthropus dawsoni* (Dawson's Dawn Man).

The Intellectual Context of the Hoax

The supposed significance of the Piltdown remains is comprehensible only within the context of evolutionary thinking in the period of their discovery. Charles Darwin's *On The Origin of Species* had been published in 1859. Though there was substantial resistance to the theory of evolution as espoused by Darwin, the book was a best seller, and many became convinced that Darwin had presented a viable mechanism, called by him "natural selection," by which plant and animal species had originated and changed through time. Though Darwin avoided in *Origin* explicitly applying that mechanism to humanity, at the end of the book, he predicted that through the application of the concept of natural selection, "much light will be thrown on the origins of man and his history."

If Darwin were correct, if all plant and animal species, including human beings, were the products of the evolutionary process of natural selection, there should be evidence of this process in the fossil record. In other words, fossil remains reflecting previous forms of humanity should be found. But what might previous forms of our species look like, and how would we recognize their bones when we find them?

By Darwin's time, it had long been recognized that the contemporary animals most closely resembling human beings, both morphologically and behaviorally,

Source: © Robert Jurmain.

were the great apes, in particular, chimpanzees. Creationists took this merely to be a reflection of God's will, while evolutionists believed that this signified that human beings and apes were closely related, sharing in deep time a common evolutionary ancestor from which we had diverged. It was argued that the feature that most clearly and significantly demarcates and distinguishes modern people from modern apes was not seemingly trivial physical characteristics, like the morphology of our hands or feet, the size of our canine teeth, or nose shape. Instead, most thinkers reasonably concluded that the single most significant distinction between people and apes was our far greater level of intelligence made possible by our much larger brains—ours are 4 times larger than those of chimps.

Because we are most significantly different from our contemporary evolutionary cousins in terms of brain size and attendant intelligence, it was further concluded that brain size was our most developed or most evolved attribute, the physical feature most changed from an ancestral state and that, therefore, must have been evolving longest. This, in turn, was taken to mean that the initial characteristic to distinguish the human from the ape line in our evolutionary chronology must have been an expanding cranial volume necessitated by an enlarging brain. As a result, when perusing the fossil record to find the first human ancestors, scientists initially expected to find evidence of a creature with an apelike body but a cranium much larger than that of an ape. Grafton Eliot Smith, head of the Anatomy Department at University College, London, in the early 20th century, went so far as to predict that a hypothetical early

human ancestor should be “merely an ape with an overgrown brain.” This view that the human brain had evolved before the features of the modern human body is labeled the *brain-centered paradigm* of human evolution.

Though it became the preferred view, mounting fossil evidence in the late 19th and early 20th centuries appeared to contradict the brain-centered paradigm. Scientists excavating for ancient human remains simply were not finding the bones of apes with overgrown brains. For example, just 3 years before the publication of *On The Origin of Species*, a discovery had been made in the Neander Valley of Germany

that appeared to throw light on human antiquity. A calvarium (or “skullcap” consisting of the top of the cranium, lacking the face and lower jaw) had been found that although as large as that of a modern human being seemed otherwise apelike, with a flattened profile, a prognathous (jutting-out) lower face, and a large ridge of bone above the eyes. The calvarium also lacked the typically steep forehead of modern humans. Similar crania were found in Europe in the 19th century and together these fossils were assigned the name *Neandertal*.

The bones of the postcranial skeletons (the bones beneath the skull) of these Neandertals belied the prediction of the brain-centered paradigm. Though there was substantial controversy concerning the precise method of Neandertal locomotion, it was clear that they were, like modern human beings and unlike the apes, upright walkers. With their apelike cranial shape, the Neandertals seemed to be not the predicted apes with overgrown brains, but something quite different.

Later, in 1891, Dutch physician Eugene Dubois obtained a calvarium and femur from an ancient stratigraphic layer on the island of Java. The skull fragment was substantially smaller than that of a modern human—at about 940 cc, it was only 65% of the modern human mean (1450 cc). However, the femur found in association with the calvarium was indistinguishable from that of a modern human. Like the Neandertals, the so-called Java Man also was not an “ape with an overgrown brain,” but apparently the reverse, an upright human with a small, apelike brain.

Thus, before the discovery at Piltdown in 1912, the fossil evidence for human evolution implied, contrary to the preferred brain-centered view, that it had been

an upright stance and bipedal locomotion, not the size of our brains and, therefore, not our great intelligence, that had early on distinguished our human ancestors from our evolutionary cousins.

The Key to Piltdown's Success

Herein lies the key behind the significance of the discovery at Piltdown. Piltdown Man presented researchers with a very ancient human ancestor—perhaps at least as ancient as Java Man and far older than the Neandertals—with a very modern-looking, large braincase but a very primitive-looking, in fact very apelike, lower jaw. Though no postcranial remains of Piltdown Man were recovered, the humanlike cranium with an apelike jaw implied that Piltdown had possessed a humanlike brain but had been apelike from the lower jaw down, a compelling bit of evidence in apparent support of the brain-centered paradigm.

Thus, in this singularly dramatic discovery, the brain-centered paradigm had been revived, all other ancestral human fossils were displaced from the main line of human evolution, and, in addition, England, formerly devoid of any significant remains of ancient human beings, had found an ancestor.

Piltdown Unmasked

The discovery at Piltdown inspired a flood of paleoanthropological investigations, launched in the predictable attempt to confirm with additional evidence the existence in the human genealogy of a precociously large and humanly configured brain associated with a still unevolved, apelike body. However, no confirming evidence was forthcoming from any post-Piltdown investigations in Africa or Asia. In fact, the only investigator able to find an ostensibly confirming fossil was none other than Charles Dawson, the discoverer of the original, who claimed to have found a similar specimen just a few miles from where he had found the original.

Due to the scarcity of any convincing confirming evidence and the distinctly singular morphology of the Piltdown remains in the context of a growing sample in the 1920s, 1930s, and 1940s of small-brained bipeds deep in the human past, *Eoanthropus* was relegated to the status of a footnote in discussions of human evolution. When, finally, definitive dating tests were developed and then applied to the remains in the late 1940s and early 1950s, the hoax was definitively revealed. The cranial fragments of Piltdown

Man were those of a modern human being, ultimately radiocarbon dated to only about 600 years ago. The mandible, whose apelike morphology seemed to support the notion that early in the evolution of our species, our human ancestors retained their simian characteristics below the all-important brain, was apelike for the rather obvious reason that it had come from an ape, specifically, a modern orangutan, intentionally broken at exactly the right place to make it appear to belong to the Piltdown cranium. Filing marks on the teeth made by a metal tool clinched the diagnosis of fraud.

The identity of the perpetrator of the Piltdown hoax is still somewhat of a mystery. Dawson's culpability seems clear, as he had much to gain (the fossil was named for him, and his fame grew as a result) and was present at every one of the discoveries at Piltdown as well as at the second site (labeled Piltdown II). Many others have been named, including highly respected scientists (Arthur Smith Woodward of the British Museum and Sir Arthur Keith, knighted for his contribution to science), a museum worker (Martin Hinton), a Jesuit priest (Teilhard de Chardin), and even a world-famous author (Arthur Conan Doyle of Sherlock Holmes fame), but the evidence is not compelling that any one of these individuals contributed to the hoax. Each had a plausible motive, sufficient expertise, and, perhaps, adequate opportunity to produce and plant the false fossils, but ultimately, the identity of the guilty party is not all that important. The important lessons of the Piltdown hoax are these: (a) Piltdown was successful because it lent support to an expected, widely accepted view of evolution, the brain-centered paradigm; (b) scientists can be susceptible to hoaxes, especially when faked data conform to and support a preferred hypothesis; and (c) science is self-correcting, and when the implications and predictions drawn from evidence that turns out to be fabricated are not realized, the hoaxes themselves are debunked and relegated to the dustbin of history. It may have taken 40 years, but this is precisely what occurred in the case of Piltdown.

Hoaxes in Archaeology: A Mysterious American Past

Hoaxers have long been busy in archaeology as well, providing ostensible evidence supporting a representation of the past that conforms better to the desires

of many. Consider, for example, the Newark Holy Stones, artifacts with Hebrew inscriptions found in 1860, immediately to the east of an authentically ancient earthwork in Newark, Ohio.

The Moundbuilder Myth

The mid-19th century was awash in speculation about who had built the thousands of earth mounds that dotted the landscape of the American Midwest. Some were massive tumuli, containing human remains buried along with an impressive and technologically sophisticated array of grave goods of stone, clay, and copper. Other earthworks had been made in the shape of animals. Serpent Mound in Ohio is one of the most impressive, a sinuous embankment of earth depicting a snake more than 405 meters (1,330 feet) in total length, from its gaping mouth to the tip of its coiled tail. Other mounds were extensive berms of earth enclosing the tops of hills. Still others had been constructed in the shape of huge, flat-topped pyramids, apparent platforms for temples or the conduct of ceremonies. Monks Mound, at the site of Cahokia, located in Collinsville, Illinois, looms 30 meters (100 feet) above the landscape and contains more than 560,000 cubic meters (20 million cubic feet) of earth, making it, by volume, the fifth-largest pyramid in the world. Monks Mound is the largest in a cluster of more than 100 found at the Cahokia site, a near-urban settlement at its peak more than 700 years ago.

Many naively believed that the native people of America could not have been responsible for the construction of these impressive earthworks because their culture was too primitive. These skeptics denied even the possibility that American Indians were capable of the methodical, coordinated labor necessary to have built the mounds. But if they had not constructed the mounds, someone else certainly must have. This led to rampant speculation in the 18th and 19th centuries concerning who that someone could have been. A host of possible ancient Old World visitors to the New World were suggested as having been responsible.

As seen in the case of Piltdown, the desire for material evidence in support of a preferred explanation fuels anthropological hoaxes. The desire to solve the “mystery” of who had built the mounds—and to solve it in a way that denied the involvement of native people—provided powerful inspiration for a number of archaeological fakes.

Moundbuilders From Israel?

The Newark Holy Stones

The “Newark Holy Stones” were found in 1860 by professional land surveyor and ardent amateur archaeologist David Wyrick in Newark, Ohio. The first artifact discovered, the so-called Keystone, looks a bit like a plumb bob with Hebrew lettering on all four of its faces. Unable to read Hebrew, Wyrick brought the object to a local reverend that he knew, John W. McCarty, who translated it. On each of its four faces, the messages read, respectively: “the laws of Jehovah,” “the Word of the Lord,” “the Holy of Holies,” and “the King of the Earth.”

An artifact with Hebrew writing on it found in association with an ancient mound site seemed to lend support to the claim that a group other than Native Americans had built the mounds. Specifically, perhaps it had been ancient Hebrews who had had been responsible for the construction of at least some of these remarkable earthworks.

There was at least one significant problem with this interpretation. Scientists who examined the Keystone soon after it was discovered, the most important being geologist Charles Whittlesey, concluded that it could not have been a genuinely ancient Hebrew artifact. The inscription had been written in an essentially modern version of Hebrew. This represented a clear anachronism in an artifact that was supposed to date to the most active period of mound construction in Ohio, some 2,000 years earlier.

Whittlesey was a highly respected scholar with significant experience investigating and excavating mound sites in Ohio. His conclusion that the Keystone was a fake was accepted by many who, as a result, viewed it as a mere peculiarity, a prank perpetrated by someone who knew it would draw attention because of public fascination with the moundbuilder mystery. Then, just 5 months after the discovery of the Keystone and its rejection by most scholars, another anomalous artifact was found only about 6 miles from the Keystone find spot, by the same fellow who found the first one, David Wyrick. Called the “Decalogue” because it bore a version of the “Ten Commandments,” this second inscribed stone rather conveniently appeared to counter precisely the primary criticism leveled at the first. This artifact’s inscription was far more convincing, bearing an archaic version of the Hebrew language dating to a time that seemed a much better fit for the period of mound construction. Rather than convincing scholars of its legitimacy,

however, this feature of the Decalogue stone was interpreted by many as evidence of fakery. How likely was it, skeptics inquired, that a genuinely ancient Hebrew artifact would be found just a few miles from where a fake Hebrew artifact had been found 5 months previously by the same individual? It seemed far more likely that the hoaxer had learned from the criticisms leveled at the first artifact and used this knowledge to produce another, more convincing piece.

Researchers Brad Lepper and Jeff Gill have delved into the details of the Newark Holy Stones and present a convincing argument for the specific motives behind them. They discovered that the Keystone and Decalogue's translator, Reverend McCarty, served under a bishop, Charles Petit McIlvaine, who had already publicly predicted that artifacts linking the moundbuilders to the Bible would one day be found. In Lepper and Gill's view, McCarty simply supplied the "proof" that fulfilled his bishop's prediction. Lepper and Gill suggest that McCarty had the fake stones made, planted them in the ground, and, perhaps, directed the artifact collector Wyrick to them. McCarty's motive may have been to lend support to his and McIlvaine's belief in an intimate connection between the native inhabitants of the Old and New Worlds, both having descended from the people of the Old Testament.

Beginning in 1872, a team of researchers led by Cyrus Thomas of the Smithsonian Institution gathered data on 2,000 earthworks in 21 states, collecting 40,000 associated artifacts. This work led to the publication of an enormous volume in 1894, proving conclusively that the moundbuilders had not been a mysterious race of settlers of North America, but were the ancestors of the native people who Europeans had encountered in their expansion across the continent in the 18th century. Thomas discussed the Holy Stones and agreed with Whittlesey's conclusion that they were fakes. The Keystone and Decalogue today are on display at the Johnson-Humrickhouse museum in Coshocton, Ohio. Though their authenticity is still championed by some, the vast majority of historians and archaeologists view them as little more than a historical curiosity.

Hoaxes in Cultural Anthropology: The Tasaday

In a short article appearing in the December 1971 issue of *National Geographic* titled "The Tasadays: Stone Age Cavemen of Mindanao," the magazine

revealed the discovery of a small group of native people living in caves on the island of Mindanao in the Philippines. These people captured the attention of *National Geographic* and were about to capture the attention of the Western world because they appeared to be the last human group on Earth untouched by modern civilization. The Tasaday seemed to represent the final remnant of a way of life that, perhaps, had characterized all of humanity for much of the history of our species. Social scientists and laypeople alike were intensely interested because, as *National Geographic* author and visitor to the Tasaday Kenneth MacLeish phrased it, the Tasaday were the equivalent of "time travelers in a time machine," individuals plucked from an ancient period and deposited in the modern world, where we could gaze at the primitive innocence we, as a species, once had.

We All Want to Be Tasaday

Worldwide interest in the announcement of the existence of the Tasaday is understandable when we consider the context of the early 1970s. Americans were in the midst of an unpopular war and middle-class youth across Europe and America were actively questioning and rejecting the materialism that seemed to dominate and define the lives of their parents. Racism and sexism were being addressed, perhaps as never before, the deleterious impacts of 20th-century technology on the environment were being recognized and assessed, and repressive attitudes about sexuality were being questioned. Many were reconsidering Western civilization as a whole, viewing it not as the pinnacle of cultural evolution, but as a hopelessly sterile existence characterized by inequality, oppression, death, and destruction.

The language and phrasing of the articles announcing the discovery of the Tasaday were a perfect match for this period of social upheaval. The 26 (or 24, depending on who was doing the counting) Tasaday seemed to be living a natural, pristine, pure way of life, as MacLeish phrased it, "much as our ancestors did thousands of years ago." The Tasaday were unpolluted by materialism, acquisitiveness, hatred, and war. They were living a way of life that many in the early 1970s wanted desperately to recapture for themselves. In her 1970 composition about the Woodstock music festival held in New York State in 1969, a cultural event that represents a coalescence of the political and social sea changes of the period, popular singer and songwriter Joni Mitchell plaintively cried out: "We've

got to get ourselves back to the garden.” The Tasadays were, in a sense, the embodiment of the “Woodstock Nation.” Their homeland and way of life were, literally and figuratively, viewed as that Edenic “garden” that so many hoped existed and to which they hoped to return.

The Tasaday were, as one wag phrased it, “paleo-hippies.” In a time when materialism was being rejected in the West, the Tasaday didn’t even have a concept of private property. Desiring nothing, they had no unfulfilled desires. Though lacking in virtually any material comforts, they were described as being a truly “affluent society.” They shared everything, they recognized no leader, and all decisions were made by friendly consensus. The Tasaday didn’t hunt or grow crops, but subsisted almost entirely on the wild plants that grew abundantly in their small territory. Perhaps most significantly, in a time when those of us in the West lived in constant fear of imminent and utter nuclear annihilation and anthropologists wondered if territoriality, aggression, murder, and war had been inextricably etched into our genes, the existence of the Tasaday challenged this pessimism. They were a peaceful people who made no weapons and who did not even have a word in their language for war.

Writing for *National Geographic*, MacLeish’s characterization of his visit to the caves on Mindanao reflects the fundamental reason why the Tasaday so captivated the Western world. Describing this friendly confrontation between bearers of Western civilization and the simple, natural people of the Philippine forest, MacLeish put it this way: “Creatures of man’s most advanced and *tormented* society, and they [the Tasaday], perhaps the last of the world’s innocents, watched each other across the full span of cultural evolution. And they felt love for each other.” It was the perfect paradox. Proud bearers of Western civilization, with its complex technologies, innumerable material comforts, enormous scientific achievements, and great social and political sophistication, were the pitiable element in this equation, facing off against the simple innocence and blissful happiness of the primitive Tasaday, a people who had nothing—except bliss and happiness. With all of our material advancements and comforts, it was we who envied them.

Upon their “discovery,” the Philippine government moved to protect the Tasaday from the depredations of the modern world. Their champion was found in Philippine official Manuel Elizalde, who held the governmental post “Presidential Assistant on National

Minorities.” Elizalde had the ear of the dictatorial ruler of his country, Ferdinand Marcos. With Marcos’s blessing, Elizalde created a 46,299-acre preserve—this, for 26 people—that was to be off-limits to loggers, miners, developers, and the vast majority of anthropologists. This was done, ostensibly, to protect the Tasaday, to allow them to continue to live their way of life unobstructed by the interference of those who might exploit them. This policy, not coincidentally, also served to isolate them from those whose only agenda was to study them. Elizalde also initiated a fundraising campaign, establishing a foundation whose purpose was to help protect the Tasaday from the outside world. It is estimated that the foundation collected more than \$35 million for this ostensible purpose.

Paradise Lost: Revelation of a Hoax

During the period of 1974 to 1986, the Tasaday remained an ensconced and insulated people, an icon of paradise lost, a living fossil reflecting the idyllic way of life abandoned by our ancestors in the devil’s bargain offered by the evolution of cultural complexity.

Then, in 1986, this neat little scenario came crashing to earth. The dictatorial regime of Ferdinand Marcos was overturned. Cronies of the regime, including Elizalde, ultimately fled, and the tens of millions of dollars he oversaw to protect the Tasaday disappeared along with him. More important, the forest preserve of the Tasaday was reopened, not to those bent on despoiling the habitat of Mindanao, but to scientists who wished to revisit the Tasaday and take the metaphorical time machine once more.

There was only one problem. In 1986, no one was living in the caves that were purported to have been the homes of the Tasaday. When surviving individuals in the original cohort of 26 were tracked down, they were found living in houses in villages, planting crops, wearing T-shirts and jeans, smoking cigarettes, and living a lifeway that was indistinguishable from other native residents of the forests of Mindanao. Most damning of all, when questioned about what had happened in the 15 or so years since the announcement of their existence in 1971 and the renewed contact in 1986, some stated that nothing at all had happened—and that, in fact, their lives as simple, primitive, nearly naked cave people had been nothing more than a bit of theater they had been

coerced into by none other than Manuel Elizalde. As one Tasaday reported:

We didn't live in caves, only near them, until we met Elizalde. . . . Elizalde forced us to live in the caves so that we'd be better cavemen. Before he came, we lived in huts on the other side of the mountain and we farmed. We took off our clothes because Elizalde told us to do so and promised if we looked poor that we would get assistance. He gave us money to pose as Tasaday and promised us security from counter-insurgency and tribal fighting.

Appalled by the apparent humbug that had taken in so many, including most anthropologists, the American Anthropological Association asked linguist Thomas Headland to organize a symposium on the Tasaday for their 1989 annual meeting. Contributions to the symposium were published in 1992 in a book edited by Headland and titled *The Tasaday Controversy: Assessing the Evidence*. Scholars involved with investigating the Tasaday in the early 1970s as well as other specialists with crucial insights about the controversy participated. Though some raised to the defense of the claim that the Tasaday at least were an isolated, distinct cultural group, most concluded from the evidence that the Tasaday had been manipulated to play the role of a primeval cave people as part of a cynical hoax.

For example, the Tasaday had been presented as a people completely isolated from their neighbors on Mindanao, whose villages, by the way, had been a mere 3-hour walk from the Tasaday caves. However, a careful reexamination of their language by linguist Clay Johnston indicated that it was virtually identical to that of their neighbors, people with whom Johnston had lived for 10 years, sharing in common 90% of their words. The claim that the Tasaday were nonagricultural and nearly completely vegetarian, lacking even simple weapons for hunting, was shown by Thomas Headland, the symposium organizer, to be improbable at best. A careful analysis showed that they could not have survived on what they were actually seen eating in the early 1970s. That they were a "Stone Age" people whose simple toolmaking was a model for the technology that characterized ancient humanity was shown to be farcical by anthropologist Robert Carniero. He pointed out that the few stone tools the Tasaday used were childish and nonfunctional. These supposed tools were further characterized by

another symposium participant, anthropologist Gerald D. Berreman, as "amateurish tools such as seventh graders might be expected to invent in response to a classroom assignment."

Finally, even if one could argue that the Tasaday had abandoned the caves only recently, there should have been in 1986 physical evidence of the kind archaeologists find reflecting past habitation, things like middens, living surfaces littered with broken bits of stone, and trash accumulations. But, as Berreman pointed out, the caves where the Tasaday were supposed to have lived for generations lacked any physical sign of human habitation. No human group is that assiduously neat, and the lack of any physical evidence of occupation of the caves seems definitive in showing that the Tasaday had never lived in them.

Elizalde ultimately absconded to Costa Rica with the Tasaday foundation money, squandering it there and dying of drug abuse in 1997. His motivation for the hoax, likely with the approval of Marcos, had been to create a situation in which a large swath of valuable forest lands could be set aside for him to control and to profit from, and a gullible world would fund his lifestyle by supplying huge sums of money for what was thought to be the worthwhile and valuable effort to protect and preserve a fascinating lifeway on the brink of extinction.

Self-Correction in Science

That the Tasaday hoax worked for 15 years is a sad testament to the shamelessness of its perpetrators. The success of the Tasaday hoax, like the success of Piltdown and the Newark Holy Stones, is emblematic, showing that hoaxes in anthropology have been successful when they gave an audience what they wanted, whether it was a preferred evolutionary ancestor, Old World visitors to the New World in antiquity, or the existence of a paradisaical way of life that reflects the essential goodness of the human species. Fortunately, the success of these hoaxes was relatively short-lived. Science is self-corrective, and the irony is clear. The hoaxes discussed here each inspired additional research, as new data with revolutionary implications always do, and this is precisely what led to their unmasking.

HOBBS, THOMAS (1588–1679)

Born April 5, 1588, in Westport, England, Thomas Hobbes claimed that his birth was premature due to his mother's fear of the Spanish Armada. Son of a minister of the Church of England, he was able to receive an education at Magdalen Hall, Oxford, from which he graduated in February 1608. Hobbes was then recommended to William Cavendish as a tutor for Cavendish's son William. Hobbes remained close to the family right up until his death at the family's home at Hardwick on December 4, 1679. Much of Hobbes's life was mired by political unrest in England; during the span of his life, the country saw the fall of the monarchy, a civil war that led to the rise of the Commonwealth, the fall of the Commonwealth, and the restoration of the monarchy. Fearing for his life, Hobbes fled to the continent in 1640, and there, he honed his philosophical skills through exchanges with Descartes and on tours of the warring principalities of Italy. He remained there until the winter of 1651 to 1652, returning only months after the publication of *Leviathan*. He used the principles of *Leviathan* to justify his taking an oath of allegiance to the Commonwealth, asserting that while he was a supporter of the monarch, he could also support any other form of government that was sufficiently powerful enough to protect his rights. Hobbes was full of contradictions: He was a royal sympathizer who supported democratic philosophies and a Christian

whose naturalistic and materialistic philosophies could be interpreted as having atheist tones.

An influential philosopher and mediocre mathematician and physicist, Thomas Hobbes laid down the philosophical framework for the philosophers of the Enlightenment. His most widely recognized piece would be *Leviathan*, which was published in England in May of 1651 while he was in exile in France. Hobbes's political theory is centered around psychological egoism, which states that each person will always act upon what he or she thinks is best for himself or herself. The fundamental axiom on which Hobbes based his theory of politics rested upon what he considered to be the natural state of man. Previously, it had been thought that governmental institutions, such as monarchies, were natural entities, but Hobbes concluded that any government was not consistent with the natural state of man. The natural state of man, according to Hobbes, was a war of all against all. Hobbes felt that this war was generated by the relative equality of each individual, in that every person more or less would be capable of destroying another. In man's natural state, Hobbes said that each person has unlimited rights; for example, they have the right to kill anyone. However, this poses a contradiction: If A has the right to kill B and B has the right to live, then it must be concluded that no one has the right to anything. Thus, according to Hobbes, people willingly invest their sovereignty (rights) into a absolute sovereign whose responsibility is to keep law and order in hopes of reducing general pain, suffering, and death, for it would be in the best interest of each individual to reduce these conditions. This investment is known as the "social contract," an idea that bases the power of government in the will of the people and was instrumental to the development of writers during the Enlightenment.

HOEBEL, E. ADAMSON (1906–1993)

E. Adamson Hoebel was an American anthropologist whose major contribution to anthropology and other social sciences was the development of the “trouble case method” for analyzing the legal systems of non-literate peoples. Prior to 1940, the legal systems of the world’s peoples were seldom studied by anthropologists, and when they were, it was a listing of rules without any data on their application. On his own and in collaboration with legal scholar Karl Llewellyn, Hoebel developed the field of legal anthropology. Major works included his dissertation on the Comanche Indians (1940), a volume on the legal system of the Cheyenne, coauthored with Llewellyn (1941), his anthropology textbook, which went through four editions (1949, 1958, 1966, 1972), a treatise on the law of nonliterate peoples, which was aimed both at professionals and students (1954), and an ethnography of the Cheyennes, designed for students (1960, an extended version appeared in 1978). *The Cheyenne Way* has been described as a classic ethnography and an opus magnum. By focusing upon the disputes and the manner in which they are resolved, and by whom, a legal system of a nonliterate society can be derived and analyzed. In *The Law of Primitive Man*, Hoebel added a time dimension, thus permitting the study of legal dynamics. In the years that followed, scholars have elaborated upon Hoebel’s approach. “The extended-case method” traced disputes back to their origins and forward, to see how new social relationships developed. The method has been applied to the study of feuding. Trouble cases, referred to as “encounters” or “episodes,” are linked in a “feud sequence” that may span decades.

Edward Adamson Hoebel, known to his friends as “Ad,” was born in Madison, Wisconsin, in 1906. He received his BA from the University of Wisconsin, his MA in sociology from New York University, and his PhD from Columbia University. Hoebel’s fieldwork was undertaken among the Comanches of Oklahoma in 1933 as a member of an ethnological field group led by Ralph Linton, his undergraduate professor. He conducted further fieldwork in 1934 with the Fort Hall Shoshones of Idaho. His dissertation on Comanche law-ways was successfully defended in 1934, published in 1940, and his PhD awarded in 1941. He married Frances Gore in 1930; she died in 1962. Although his anthropology advisor was

Franz Boas, his intellectual mentor was Karl Llewellyn, a distinguished jurist well-known for devising the Commercial Code and advocating a position known as “legal realism.” Hoebel liked to tell the story of how Boas sent him to meet with Llewellyn, which he did in June 1933, to discuss his Comanche research. Llewellyn advised Hoebel to focus on how disputes are settled, an approach known among legal anthropologists as “dispute settlement processing.”

Hoebel and Llewellyn together conducted field investigations during the summer of 1935 among the Northern Cheyenne. In 1936, Hoebel returned for an additional summer’s work. Later fieldwork was with the Pueblo Indians of New Mexico, 1945 to 1949, and in West Pakistan in 1961. Hoebel taught from 1929 to 1948 at New York University, and from 1948 to 1954 at the University of Utah, where he was chair of the department of anthropology and dean of Arts and Sciences (1953–1954). His next position was at the University of Minnesota, where he taught until 1972. He chaired the department until 1969, for a total of 15 years. He was elected President of the American Ethnological Society in 1946 and President of the American Anthropological Association in 1957. After retirement, he served as an adjunct professor at the University of Minnesota and a visiting professor at the University of Arizona. He attended professional meetings where he was the featured speaker, such as the Law and Society Association (June 1982). In 1973, this association had dedicated an issue of their journal to him. E. Adamson Hoebel died at his home in St. Paul, Minnesota, on July 23, 1993, at the age of 86. He was survived by his wife of 30 years, Irene Holth.

HOMINIZATION, ISSUES IN

One of the most important discoveries of recent times, related to our origins, is the verification of a close genetic affinity between human beings and chimpanzees. Such affinity is so significant (98.8%) that it is estimated that both phylogenetic lines that led to the two species had a common ancestor approximately 6 to 8 million years ago. Since that moment, and after the branching occurred, begins the most amazing and passionate history, that of our own family.

The “hominization process” refers to the origin and evolution of the hominid family (forms that comprise both our ancestors and ourselves). When trying to reconstruct this process, paleoanthropology acquires an especial relevance, because while giving us the historic evolutionary fundamentals of man, it shows us the same basics of anthropology as science. If the uniqueness of this is its approach to man as a bio–psycho–socio–cultural unity, that of paleoanthropology resides in its intent to answer the question of how this unity was developed.

Hominization was not only a process of biological transformation nor a simple adding of unidirectional causes and effects. On the contrary, we think that this process was a complex event, characterized by the succession of particularly significant synergic phenomena resulting from a dynamic interaction of biological, psychological, spiritual, social, and cultural variables.

Our knowledge about this process has undergone remarkable improvement during the last decades. Nevertheless, there are still some questions of complex solution. One of them derives from the fact that when we go back in time to track down our biological past in search of our own family first members, we

face a great difficulty in identifying them in the fossil record. In our opinion, the main reasons for this difficulty are the following:

1. The material known until now, between 4 to 8 million years ago, is barely representative due to its scarcity and to its being usually fragmented and deteriorated.
2. To define which are the physical features that show hominid nature in a fossil is an act always conditioned by each historical moment ideology.
3. Despite the current establishing of these features, the valuations of fossils’ anatomic traits are so varied that they do not obtain consensus among scientists.

The first reason becomes obvious if we think about the amount and quality of available material to be studied and analyzed by specialists. As for the second, we discuss below two illustrating occurrences: the famous Piltdown “discoveries” and the one performed by the so-called ramapithecines. In both cases, we will see how they were highly valued in their moment, for they clearly fulfilled the expectations of the time. Finally, we will discuss the varied interpretations supported at present concerning the finds of likely hominids with over a 4-million-year dating.

In the first decades of the 20th century, scientists thought that the most significant hominization phenomenon was the development of the brain. In this way, the existence of a decisive step or “cerebral Rubicon” was supposed, between 700 to 800 cc, the so-called step to reflection. Therefore, a skull fossil with a cranial capacity below 700 cc could not be regarded as human, while one over 800 cc could.

This explains the impact that the Piltdown “discoveries” had at their time. These “discoveries” were made in Sussex, England, including a modern-looking braincase, with cranial capacity over 800 cc, and a very primitive lower jaw. It was regarded as obviously “human” and was named *Eoanthropus* (“The Dawn Man”).

For 40 years, the Piltdown “discoveries” were considered legitimate. But in 1953, the British Kenneth Oakley, using the “fluorine technique” on the bones, proved that owing to their different fluorine percentages, those fragments could not belong to a single individual. In fact, it would be soon found out that those “discoveries” were fakes, and the whole affair turned out to be a big fraud. The braincase had actually

belonged to an Upper Pleistocene individual, while the jaw came from a modern orangutan, deliberately altered to make it look primitive and ancient.

Some years later, “ramapithecines” would come on the scene. Ramapithecine fossil fragments were considered representative of the “first hominid” and had unanimous acceptance during the 1960s and 1970s, then they were completely abandoned. This episode’s significance in paleoanthropology history deserves more detailed discussion.

In 1932, during a Yale University expedition to Siwalik Hills (north of India), graduate student G. Edward Lewis found a maxilla with two first molars, two premolars, and canine and incisor teeth alveoli. From the alveoli shape, it could be derived that the canine barely exceeded other teeth in height and that the incisor was inserted almost vertically, reducing its prognathism.

The aforementioned features led Lewis to name this specimen *Ramapithecus brevirostris* (*Rama*, alluding to a hero in Indian mythology; *pithecus*, ape; and *brevirostris*, Latin, “short face”). When trying to place it within the family it belonged, Lewis recorded, “hominid”? This question was left without an answer because nobody cared about it in those days. It is obvious that if *Australopithecus* was not regarded as a hominid, much less would be the more primitive *Ramapithecus*. Almost 30 years were necessary for the topic to be considered again during the 1960s.

In 1961, Helsen Mukuri, Louis Leakey’s first field assistant, found a fragment of a left upper maxilla that still had the canine tooth, the first premolar alveolus, the second premolar, and the two first molars. This find took place in Fort Ternan, northeast of Lake Victoria (Kenya). Leakey immediately noticed the hominid characteristics of the finding and named it *Kenyapithecus wickeri*, after Kenya Colony and the man who owned the site, Charles Wicker.

In his first scientific communication, Leakey called attention to the resemblance between *Kenyapithecus* and *Ramapithecus*, pointing out that both had features that put them closer to hominids than to pongids. Yet he gave greater significance to *Kenyapithecus*.

Meanwhile, Elwyn Simons, of Yale University, would revitalize the *Ramapithecus* significance as probable first hominid, due to its small canines, its reduced diastema, its thick dental enamel, and its nonprotruding short face (unlike apes). Later, in 1963, David Pilbeam joined the team. Together, they would carry out a remarkable synthesis task by

observing that not only were *Ramapithecus brevirostris* and *Kenyapithecus wickeri* alike, despite the very long geographic distance between them, so were fossils found in other locations (Greece, Turkey, Hungary, to name a few). By this reason, they proposed to include all of them into the generic name *Ramapithecus* (which had priority because of its being coined first).

Furthermore, Simons and Pilbeam endorsed the idea, speculative but in agreement with the thoughts of the time, that the canine reduction in *Ramapithecus* was not an isolated trait. It was, as Darwin had expressed it, a result of a greater use of the hands owing to the manufacturing of tools and weapons. This would suggest bipedalism.

By then, the “granivorous hypothesis” was known, proposed by Clifford Jolly of the University of New York, who, in the 1970s, provided valuable data gathered from his studies on the gelada baboon (*Theropithecus gelada*) of Ethiopia. These data reasserted the significance of the canine reduction (thus consolidating *Ramapithecus* as likely first hominid). However, they also showed that this reduction was not a result of a greater use of the hands (as the Simons and Pilbeam hypothesis propounded), but of ingesting tough foods, such as grains and seeds. To eat this kind of food requires premolar and molar movement from side to side, for grinding it, an impossible procedure with very large canines.

In the meantime, during the 1960s, there were interesting innovations in the biochemistry, molecular biology, and genetics fields. These innovations would have a strong influence regarding *Ramapithecus* within the primate phylogeny. In 1962, Emile Zuckerkandl and Linus Pauling proposed to apply molecular biology to the study of human evolution. They thought the molecular study could provide equal or greater information than fossils in matters involving the construction of genealogical trees. Thus, “molecular anthropology” was born. By then, biologist Morris Goodman, of Wayne State University (Detroit), had published some data about the immunological properties of albumin. These properties showed that chimpanzees, gorillas, and human beings were closely related, while gibbon and orangutan were more distant relatives of that group.

Some time later, in 1967, American biochemists Vincent Sarich and Allan Wilson, of the University of California (Berkeley), studied the chemical structure of protein molecules in gorillas, chimpanzees, and human beings. As a result of this work, they

concluded that the perceived differences among them could give some accuracy about the time their evolutionary lines drifted apart. In this way, the “molecular clock” was created, based on the principle that when these two groups began to split, each of them started to accumulate mutations that would create differences between them. Therefore, the greater the elapsed time, the more accumulated differences between the two groups would exist.

By applying the “molecular clock,” estimates were made about the branching of the lines that led to present chimpanzees and hominids. This branching would have occurred approximately 5 million years ago. Also, taking this split into account, for molecular biologists, it was clear that to search for a hominid in the fossil record before this branching was useless, despite appearances that might suggest the contrary. This obviously made *Ramapithecus*, at 14 million years ago, lose every chance for being regarded as a hominid, although most paleoanthropologists still believed that at the time.

In fact, paleoanthropologists regarded *Ramapithecus* as a hominid for almost 20 years. But in the early 1980s, some revealing finds would be made, particularly face fragments of two fossils named *Sivapithecus*. One of these was found in Turkey, and Pilbeam and his team found the other one in Pakistan. At once, the resemblance between *Sivapithecus* and *Ramapithecus* was recognized. Furthermore, attention was paid to the new fossil resemblance to the present orangutan. Then, it became obvious that *Ramapithecus* was more related to the phylogenetic line that led to present orangutans than to hominids.

This corroboration, along with the available biochemical, molecular, and genetic evidences, convinced David Pilbeam and most paleoanthropologists in the following years that *Ramapithecus* could no longer be regarded as a hominid. Moreover, nowadays its name has been completely lost, being absorbed by *Sivapithecus*.

Today, there is ample consensus in the international scientific community that bipedalism alone is a clear identifying trait for the hominid nature of a being. It is an anatomic change of major importance not only due to what it means in itself but because it became a “trigger” of significant later changes. Yet even agreeing with this point, some authors consider the possibility that early hominids did not develop bipedalism, although they had dental modifications (for example, the canine reduction) that could be

regarded as an indicator of the beginning of the evolutionary process that led to modern humans.

Fortunately, the last 12 years have been especially plentiful for findings of probable hominids 4 to 7 million years old. Here, we will proceed from the more recent to the older ones, starting with the only one that is indisputably hominid. We speak about the one found in 1995 by Meave Leakey, of the Kenya National Museum, and her team, southeast of Lake Turkana in Kenya, named *Australopithecus anamensis* (*anam* means “lake” in the Turkana language). The found materials were a jaw, some face and forearm fragments, and a tibia, dated between 4.1 and 3.9 million years ago. It is the oldest of all australopithecines known until now.

Unlike chimpanzees, which have a deep oval depression in the lower part of the humerus against which the ulna is flexed to improve the elbow articulation strength and make possible the typical displacement on the knuckles, *A. anamensis* lacks this feature. Moreover, the anterior ridge of its tibia is a clear indicator of bipedalism.

Also in the 1990s, more precisely between 1992 and 1993, Tim White, of the University of California (Berkeley), directed a research project in Middle Awash, Ethiopia, where his team discovered hominid fossils in the Aramis Basin. Afterward, these fossils were named *Ardipithecus ramidus* (*Ardipithecus* means “ground primate,” and *ramidus* means “roots” in the Afar language). It was dated 4.4 million years ago, and from the kind of related fauna, its habitat was a densely wooded zone.

At first, the occipital hole location led the finders to think that *Ardipithecus* was biped, which would have made it the oldest hominid known up to that moment, but new studies do not seem to corroborate this idea. However, the hominid nature of *Ardipithecus* could reside in its canine reduction.

Between 2001 and 2004, Tim White, together with Gen Suwa, of the University of Tokyo, and Ethiopian paleontologist Yohannes Haile Selassie, of the Natural History Museum of Cleveland (Ohio), found teeth and several bone fragments. At first, they were attributed to an older and more primitive variety of *Ardipithecus ramidus*. Afterward, these fossils were confirmed to belong to a different species, *Ardipithecus kadabba*, with an established antiquity of 5.2 to 5.8 million years. In the opinion of these authors, *A. kadabba* could have been the last common ancestor of chimpanzees and hominids.

In October 2000, a French-Kenyan team directed by Martin Pickford, of the Community Museums of Kenya, and Brigitte Senut, of the National Museum of Natural History (Paris), found some fossils within the Lukeino Formation at Tugen Hills (Kenya). These fossils comprised small mandibular fragments, isolated teeth, manual phalanxes, and upper and lower limbs bones of several individuals. They were named *Orrorin tugenensis* (*Orrorin* means “original man” in the Tugen language) and dated about 6 million years ago.

While its canines are long and the arms bones and the fingers show climbing adaptations, *Orrorin tugenensis* was probably biped. Its lower limbs were strong, and it had a long femoral neck, with a groove in its back, a possible consequence of the pressure exerted by the obturator externus muscle during bipedal locomotion.

In July 2002, a finding of the prior year was published. Michel Brunet, of the University of Poitiers (France), and its French-Chadian team made this finding in the Toros-Menalla site, Djurab Desert, northern Chad (Central Africa). A well-preserved skull, two maxilla fragments, and three teeth were named *Toumai* (“hope of life” in the Goran language) and scientifically classified as *Sahelanthropus tchadensis*. Potassium-argon or paleomagnetism could not be applied, but the surrounding fauna were compared to that of Lukeino, at Tugen Hills (6 million years), and that of Nawata, at Lothagam (5.3–7.4 million years). As a result of this, *Toumai* antiquity was estimated between 6 and 7 million years ago (closer to the last figure).

The fossil shows a real “mosaic of characters,” a mix of both primitive and advanced features. In the opinion of Bernard Wood, of George Washington University, the front of the *Toumai* skull is that of a true australopithecine, while the back is that of a chimpanzee. For Michel Brunet, the traits that suggest its hominid condition are the face structure, the kind of superciliary arches, and the small canines. Since there are not postcranial bones, nothing can be said about its locomotion mode, save the fact that by its occipital hole location, Brunet maintains that *Toumai* probably had been biped.

However, Milford Wolpoff, of the University of Michigan, John Hawks, of the University of Wisconsin, and the aforementioned Martin Pickford and Brigitte Senut disagree with Brunet; they claim that the indicated traits do not ensure a hominid diagnostic in any way. Thus, the canine smallness, for example, would not be such because its width is similar to the

mean of chimpanzee males or females and of gorilla females. On the other hand, while these authors set aside the continuous supraorbital torus as a result of strong sexual selection, as Brunet states, they think that the size and form of the supraorbital structures are a mechanical response to strain from anterior teeth.

But Brunet disregards that *Sahelanthropus* had a powerful masticatory complex. Based on experimental investigations that seem to demonstrate that the strains exerted by mastication on primate eyebrow arches are always very small, too small as for generating bone growth responses, he firmly claims that the supraorbital size is due to a strong sexual selection. For Brunet and his colleagues, *Toumai* is indisputably the oldest hominid ancestor known up to date. If it were so, it would show that first hominids had a much greater geographic dispersal than what was thought until now.

Undoubtedly, it is very difficult for authors to establish a distinction among the members of the oldest ancestors of present chimpanzees, the members of the oldest hominids, and the ways these two lines drifted apart. The whole is a real “Gordian knot” if we consider its remarkable complexity. The distinction between these two groups always depends on the evaluations of different physical characters authors could make. When something is significant for some researchers, sometimes it may not be so for others. Owing to this, the chances of conciliation in these matters are rather complex because, in common practice, authors tend to overvalue the significance of their own findings.

Thus, Martin Pickford and Brigitte Senut think that *Orrorin tugenensis* would be the common ancestor of all hominids, while *Ardipithecus* would be the common ascendant of australopithecines, not of *Homo*. On his part, Tim White rejects this interpretation, questioning the *Orrorin* hominid status and regarding it as a likely ancestor of present chimpanzees. On the other hand, for Michel Brunet, *Sahelanthropus* is the oldest hominid ancestor known until now, while White regards it as a kind of archaic ardpithecine, and Wolpoff, Hawks, Pickford, and Senut disregard it as a hominid candidate, assuming it is an ape, probably a gorilla female ascendant.

These varied interpretations of the same facts show the high degree of subjectivity existing in the studies of our origins. Certainly, in paleoanthropology there is not an objectivity concept equal to the Newtonian physics-mathematics one. Is all this a

display of paleoanthropology vulnerability as a scientific discipline? We do not think so. On the contrary, we are sure that the variety of opinions and discrepancy among authors is proper to science and, without doubt, enriches the discussion. Advancements of knowledge of our past have always happened, and they will keep happening, as a consequence of hypotheses modifications and their adjustment to new data or new available information. Only in this way will paleoanthropology keep achieving increasing acknowledgment at the scientific level.

In time, the best, most-convincing explanations are the ones that last, while the others are put aside. But frequently, an explanation that had been put aside some time before is revitalized afterward with more available information, or a good explanation is replaced by a better one. If this is absolutely natural in science, we must understand that the same will happen in such a young discipline as paleoanthropology.

The available fossil documentation related to first-hominid origin shows great complexity. No morphological discontinuity is observed, and, as we know, in continuity it is very hard to establish clear differences. Besides, if their evolution was not linear but treelike, as most authors propound nowadays, we must think of a significant diversification of forms, in such a way that some hominid-like anatomic traits could have existed in several groups at the same time. If it were so, it would be extremely hard to identify which of them first became *Homo*.

Surely, the discussion about the “first hominid” will not end. Nevertheless, we think it is important to point out that we run the risk of “not seeing the woods for the tress,” as the saying goes. Hence, our opinion is that beyond any singularity of character and relevant significance of the “first hominid” determination (if this were possible), we must not lose sight of an even more significant fact: the process as a whole. The significant thing is the process, and this is indisputable. Very slight differences at the beginning would later increase progressively in changing the phylogenetic line, which led to something absolutely original. It is the process as a whole, and not just a moment of it, that explains our present nature. We are what we are because we have a long and complex evolutionary history behind us.

HOMINIDS

Hominoids are the superfamily to which apes and humans belong. Hominoids are distinguished from cercopithecoids (Old World monkeys), the catarrhine group to which they are most closely related, in having primitive nonbilophodont molars, larger

Source: © Robert Jurmain.

brains, longer arms than legs (except in humans), a broader chest, a shorter and less flexible lower back, and no tail. Many of these specializations relate to a more upright posture in apes, associated with a greater emphasis on forelimb-dominated vertical climbing and suspension.

Hominoids can be classified into two families: the Hylobatidae, which includes gibbons and siamangs, and the Hominidae, which includes the great apes and humans. The gibbons and siamang (*Hylobates*) are the smallest of the hominoids

(with average body weights ranging from 5–11 kg), and for this reason, they are sometimes referred to as the “lesser apes.” The 12 or so species are common throughout the tropical forests of Asia, ranging from southern China to the Indonesian islands. They are remarkable in having the longest arms of any primates, being 30% to 50% longer than their legs. This is related to their highly specialized mode of locomotion, called *brachiation*, in which they progress below branches using only their forelimbs to swing from support to support. Gibbons are specialist fruit eaters, while the larger siamang incorporates a higher proportion of young leaves in its diet. Hylobatids live in monogamous family groups, in which males and females are similar in size (unlike most catarrhines). Both sexes defend a territory, mainly through complex vocalizations or songs (with male and female pairs of most species producing a duet), which serve to advertise their presence to neighboring pairs. Siamangs have large specialized throat sacs that they inflate during calling. As in Old World monkeys, hylobatids sit upright on branches to sleep, resting on their ischial callosities (i.e., sitting pads on the buttocks), rather than sleeping in nests like great apes.

The great apes include the orangutan (*Pongo*) from Asia and the gorilla (*Gorilla*) and chimpanzees (*Pan*) from Africa. These were formerly included together in their own family, the Pongidae, to distinguish them from humans, who were placed in the Hominidae.

A white-handed gibbon (*Hylobates lar*) in the forests of Thailand

However, recent anatomical, molecular, and behavioral evidence has confirmed that humans are more closely related to the great apes, especially the African apes, and for this reason most scientists now classify them together in a single family, the Hominidae. The orangutan is restricted to the tropical rain forests of Borneo and Sumatra. Traditionally, the Bornean and Sumatran populations, which are morphologically and behaviorally quite distinct, have been separated as subspecies, but there is growing support to recognize them as two separate species, *Pongo pygmaeus* and *P. abelii*. They are large (35–80 kg) arboreal primates that climb cautiously through the trees using all four limbs for support. When they descend to the ground, they move quadrupedally, with clenched fists, or bipedally, with the arms raised for better balance. Orangutans subsist mainly on ripe fruits, but they do eat a variety of leaves and small animal prey. Modified sticks are used as simple tools by Sumatran orangutans to extract honey, insects, and seeds as food sources. As is typical of other great apes, they lack ischial callosities and build simple nests to sleep in at night. Adult male orangutans are about twice as heavy as females, and the sides of their faces are adorned with huge fatty flaps. Orangutans are the least sociable of the hominoids and tend to lead solitary lives. Males aggressively defend their territory from other males, which encompasses the ranges of several female consorts. The male long call, a series of reverberating grunts, which can be heard at a distance of 1 km, serves to attract receptive females.

An infant orangutan (*Pongo pygmaeus pygmaeus*) from Borneo

A young male gorilla (*Gorilla gorilla*) knuckle-walking

The gorilla, the largest of the hominoids (70–175 kg), has a disjunct distribution in tropical Africa. Because of their great size, gorillas are almost entirely terrestrial, although females and young individuals frequently climb trees. Nests are often built on the ground. They move quadrupedally, and like chimpanzees, the hand is specialized for knuckle-walking, in which the weight of the animal is borne on the dorsal surface of the middle joints of the fingers. Three subspecies of gorillas are generally recognized: mountain gorillas (*G. gorilla beringei*), from the volcanic highlands of Uganda, Rwanda, and Democratic Republic of Congo; western lowland gorillas (*G. gorilla gorilla*), from West Africa; and eastern lowland gorillas (*G. gorilla graueri*), from the Democratic Republic of Congo. Mountain gorillas eat a variety of leaves, stem, and roots, while lowland gorillas eat a greater proportion of fruits and insects. Groups consist of a dominant male, called a “silverback” (because of the silvery white hair on their backs and hips), as well as several adult females, subadults, and infants. The silverback male defends the troop from neighboring groups, which have overlapping home ranges.

There are two species of chimpanzees, the common chimpanzee (*Pan troglodytes*) and the bonobo or pygmy chimpanzee (*Pan paniscus*). The common chimpanzee is widely distributed in the forests and

woodlands stretching across equatorial Africa, while the bonobo is restricted to the tropical rain forests of the Democratic Republic of Congo. Bonobos differ from the more familiar common chimpanzee in having a more slender build, with longer limbs (despite their name, they are not smaller than common chimpanzees); the face is black with pink lips, the hair on top of the head is parted in the middle, breasts are more protuberant in adult females, and they are more adept at walking bipedally. Both species feed and build their nests in trees, but they mostly travel on the ground. Chimpanzees have

an eclectic diet of fruits, leaves, insects, and small vertebrates. Common chimpanzees also include meat in their diet, which they obtain by hunting small to medium-sized mammals, especially colobus monkeys. Tool-using behaviors are common, and more than a dozen simple tool types have been identified. Differences in tool use and other behaviors between populations of common chimpanzees have led some researchers to interpret these as cultural traditions. Examples include termite fishing in Tanzania and the use of rocks to crack nuts in West Africa. Chimpanzees are gregarious and sociable, and they live in large multimale-multifemale communities (20–200 individuals), which divide into smaller subgroups (3–15 individuals) for foraging. Common chimpanzees have a hierarchical social structure, in which males maintain their dominance through intimidating displays and overt aggression; they have been known to kill members of other communities. Bonobos are much less aggressive and are able to reduce tension within the group through more intensive use of sexual behavior.

HOMINID TAXONOMY

The taxonomic classification system developed by Carl Linnaeus (1707–1778) is still used in modified form today. It organizes all living things into a hierarchical system composed of different levels (*taxa*). These levels are kingdom, phylum, class, order, family, genus, and species. The system is also used for classifying human beings.

Humans have been included as members of the class of mammals. They also belong to the order of primates, which includes apes. Humans are included in a superfamily called *Hominoidea*. The *Hominoidea*, or apes, include humans, chimpanzees, bonobos, gorillas, orangutans, gibbons, and siamangs and their prehuman ancestors, until a common ancestor is found.

The apes are often divided into two families: *Pongidae* and *Hylobatidae*. Because there is relatively little genetic difference between them, many scientists put them into a single family, the *Pongidae*.

The current controversy over hominid taxonomy involves the issue of the evolutionary lineage of humans and other apes traced back to a common ancestor in remote time. It is focused on the place of humans in nature and the evolutionary process that produced both humans and apes.

Paleoanthropologists believe that the common ancestors of humans and apes lived between 11 million and 13 million years ago. As new fossils have been uncovered, there has been difficulty deciding where to place them. In the hominid taxonomy, the bipedal apes—all of the fossils as well as living humans—would fall into the group *Hominini*. Fossils such as *Australopithecus*, *Ardipithecus*, *Kenyanthropus*, and *Homo habilis* would also fall into this category.

To what exactly should the terms *hominoid*, *hominid*, and *hominin* refer? In general, *hominoid* refers to the order of primates. The term *hominid* refers to the human side of the family *Hominidae*. It is composed of all humans and those ancestors back through the generations to the common ancestor that humans share with the apes.

The term *hominin* (singular), or *hominini* (plural), refers only to human lineages. Thus, humans are *hominini*. However, *hominini* are included in the

group of hominids, which includes both humans and their prehuman ancestors through to a common ancestor also related to the apes.

In the old system, *hominid* refers solely to the bipedal ape lineage. The hominid in current understanding includes both the lineages of the apes back to a common ancestor and the lineages of humans back to a common ancestor.

— Andrew J. Waskey

HOMO ANTECESSOR

Homo antecessor is the designation given a fossil hominid from the Lower Pleistocene of Atapuerca, Spain, defined in 1997 by Bermúdez de Castro, Arsuaga, Carbonell, Rosas, Martínez, and Mosquera, in *Science* magazine. The name *antecessor* is the Latin word meaning “explorer,” “pioneer,” or “early settler.” Assigning this name, they emphasized that these hominids belong to the first population as yet known in the European continent. The fully modern midfacial morphology of the fossils antedates other evidence of this feature by about 650,000 years. The midfacial and subnasal morphology of modern humans may be a retention of a juvenile pattern that was not yet present in *Homo ergaster*. Consequently, *Homo antecessor* may represent the last common ancestor for Neandertals and modern humans.

From 1994 to 1996, nearly 80 human fossil remains were recovered from level six (*Aurora stratum*) of the Pleistocene cave site of Gran Dolina (TD), Sierra de Atapuerca, Burgos, Spain. These remains were found in sediments located about 1 m below the Matuyama-Brunhes boundary. In 1997, Bermúdez de Castro and his colleagues described the TD6 fossils and defined a new species, which exhibits a unique combination of cranial, mandibular, and dental traits. Midfacial topography shows a modern pattern and infraorbital surface with true canine fossa. The supraorbital torus is double-arched. The superior border of the temporal squama is convex, and there is the presence of a styloid process. The mylohyoid groove extends anteriorly nearly horizontal and courses into the mandibular body, the thickness of which is clearly less than that of *H. ergaster* and *Homo habilis* s.s. There is an absence of alveolar prominence at the M1 level.

Source: Photo by Eustoquio Molina.

The extramolar sulcus is narrow. The lateral prominence is smooth and restricted to the level of M2. The design of the inner aspect of the corpus is similar to that of European Middle Pleistocene fossils. Mandibular incisors are buccolingually expanded with respect to *H. habilis* s.s., but postcanine teeth are smaller and within the range of *H. ergaster*, *Homo erectus*, and *Homo heidelbergensis*. The maxillary incisors are shovel-shaped. The mandibular canine is mesiodistally short.

The holotype is a fragment of right mandibular body with M1, M2, and M3 (ATD6–5) and an associated set of teeth from the same individual. Holotype and paratypes are provisionally housed in the Museo Nacional de Ciencias Naturales, Madrid, Spain. The final repository of the fossils is the Museo de Burgos, Spain.

HOMO ERECTUS

Homo erectus (literally “upright man”) is an extinct hominin that lived between 1.8 million and 50,000 years ago. The first fossil found of this species (the type specimen) was a skullcap discovered in 1891 by Eugène Dubois. However, the species was not named until 1894, after a femur (thigh bone) was discovered not far from the skullcap. The femur was nearly identical to that of a modern human, prompting Dubois to name a new species: *Pithecanthropus erectus* (literally “upright ape-man”). Both fossils were found in Trinil, Java. The type specimen was named “Trinil 2” and the femur “Trinil 3.” They are more commonly known as “Java Man.”

In 1927, Davidson Black named a new species *Sinanthropus erectus* (literally “Northern upright man”), based on a tooth discovered at Zhoukoudian near Beijing (Peking), China. The later discovery of 14 calvaria (skull caps), limb bones, and many more teeth strengthened his claim. One of these calvaria became better known as “Peking Man.” As more fossils of *erectus*-like hominins were discovered, paleoanthropologists began to recognize the similarities between *Pithecanthropus*/*Sinanthropus* and specimens that had been assigned to the genus *Homo*. Eventually, both *Pithecanthropus* and *Sinanthropus* fossils were subsumed into the species *Homo erectus*.

The morphology of *Homo erectus* changed very little over its 1.8 million years of existence. Compared with australopithecines and earlier *Homo*, *Homo erectus* had smaller teeth, a shorter face, and a humanlike projecting nose. The numerous skulls that have been discovered show a significant increase in brain size compared with earlier hominins. On average, the cranial capacity of *Homo erectus* was about 900 cc, although its range (750 cc–1,250 cc) overlaps that of modern humans (1,000 cc–2,000 cc).

Compared with modern humans, *Homo erectus* possessed a robust and somewhat primitive-looking

skull, face, and dentition. In general, the skull is long, and the forehead is low in profile. The face has marked brow ridges, and the back of the skull has a marked projection for attachment of strong neck muscles. The skull bones are thick compared with modern humans. Many of the Asian specimens (in particular) exhibit a sagittal keel, a ridge running along the top of the skull. All *Homo erectus* specimens lack the projecting chin of modern humans.

Their robusticity notwithstanding, below the neck *Homo erectus* looked very much like modern humans. Much of what we know about their postcranial skeleton (below the skull) comes from a nearly complete skeleton from Lake Turkana, known as “WT 15000” or “Nariokotome Boy.” Nariokotome Boy would have been quite tall if he had reached adulthood (perhaps 180 cm, or 6') but the average height of *Homo erectus* was about 170 cm (5'7"). This size represents a dramatic increase in stature compared with earlier *Homo*. Postcranial remains establish that *Homo erectus* was a committed biped with none of the adaptations to tree climbing observed in earlier hominins. It has been suggested that their somewhat narrower hips indicate that there were more efficient bipeds than the average modern human.

Compared with earlier hominins, *Homo erectus* exhibited greater control over its environment. This species developed a more sophisticated tool kit and may have mastered how to control fire. In addition, it was very likely the first hominin to move outside Africa. *Homo erectus* is known for developing Acheulean tools. These tools are found in high densities in Africa, Europe, and western/south Asia and are rare in East Asia. Like the Oldowan tools used by *Homo habilis*, Acheulean tools did not have specialized purposes. The Acheulean hand axe (a pear-shaped tool with sharp edges on all sides and a picklike point) was likely a kind of “Swiss Army knife” used to cut, scrape, pound, and dig. In addition to hand axes, the Acheulean tool kit included cleavers, scrapers, and notched tools. The greater diversity of tools likely indicates greater reliance on them.

Where and when hominins first began to use and control fire is the topic of much disagreement. Some paleoanthropologists attribute this innovation to *Homo erectus*. The earliest, although highly questionable, claim comes from East Africa (Koobi Fora) and dates to about 1.5 million years ago. Other, also dubious evidence comes from South Africa (Swartkrans), dating to 1 million years ago. Until recently, the best-supported

evidence was said to come from Zhoukoudian, in China, dating to between 400,000–500,000 years ago. However, a recent reanalysis of this evidence concluded that there is no direct evidence of in situ burning. So the jury is still out on whether or not *Homo erectus* was the first hominin to have had controlled use of fire.

Other cultural aspects of *Homo erectus* are also strongly debated among paleoanthropologists. While some hypothesize that *Homo erectus* was a big-game hunter, others do not agree. This is also true of the hypothesis that *Homo erectus* constructed shelters. Both the evidence of the “shelters” and the interpretation that *Homo erectus* was responsible for making them have come under scrutiny. So far, no hominin remains have been associated with what some consider the earliest evidence for man-made shelters. Finally, some claim that *Homo erectus* used watercraft. This is based on evidence for their occupation of islands in Southeast Asia, like Flores, where Acheulean tools (but no hominins) have been found dating to more than 800,000 years ago.

Homo sapiens excluded, *Homo erectus* was the farthest ranging of all the hominins. Their skeletal remains or their tools are found in Europe, India, and East and Southeast Asia. Evidence suggests that *Homo erectus* was the first hominin to migrate out of Africa (although recent discoveries in Dmanisi, Georgia, may ultimately disprove this). The oldest *Homo erectus* fossil from Africa is 1.6 million years old. In Java, scientists have recently dated fossils to 1.8 million years ago. If these dates are correct, it indicates that *Homo erectus* left Africa much earlier than once believed. Recent dates from different sites in Java (Ngandong and Sambungmacan) suggest that *Homo erectus* existed for 250,000 years longer than once believed. If correct, these dates would indicate that the species survived in Southeast Asia until between 27,000 and 53,000 years ago. Since modern humans were also present in Southeast Asia by this time, it would mean that the two species coexisted.

The status of *Homo erectus* as a species has a long history of controversy. The first *Homo erectus* fossils found were not accepted as hominins, because they had small brains and at that time it was thought that humans evolved large brains before becoming bipedal. Later, as more fossils of *Homo erectus* and other hominins were found, the validity of *Homo erectus* as a taxon was accepted. But more fossils meant more variation, and by the 1970s it was suggested that *Homo erectus* be split into more than one

species: *Homo ergaster* for the African fossils, *Homo heidelbergensis* for the European fossils, and *Homo erectus* for the Asian fossils. For those who advocate splitting the species, *Homo ergaster* represents the common ancestor of *Homo erectus* and *Homo heidelbergensis*; *Homo heidelbergensis* then gave rise to Neandertals (or Neandertals and modern humans), while *Homo erectus* in Asia became extinct. In many respects, much work still needs to be done to define the species and its culture.

HOMO ERGASTER

Homo ergaster (literally “work man”) is an extinct hominin that lived in Africa about 1.9 to 1.6 million years ago. The species was named by C. Groves and V. Mazak in 1975, based on the discovery of a mandible known as “KNM-ER 992.” This fossil for which the species is named was found at a site called Koobi Fora, Kenya. It is 1.5 million years old. Important specimens assigned to this species include a very well-preserved cranium (KNM-ER 3733), which is 1.7 million years old, and the famous “Turkana Boy” (KNM-WT 15000), a nearly complete skeleton, which is 1.6 million years old.

As the name suggests, *Homo ergaster* was a toolmaker. Its fossil remains are typically found in association with stone tools ascribed to the Acheulean tool

tradition. These tools consist of primarily hand axes (large tear-drop-shaped stone tools) and cleavers. It was once thought that the invention of these tools led to the spread of early humans outside of Africa. However, it is now known that hominins migrated out of Africa before developing Acheulean tools.

Homo ergaster is a controversial species. Some paleoanthropologists include it within the species *Homo erectus*, while others consider it a distinct species. Those who agree that there are two species split *Homo erectus* into early African and Asian species. *Homo ergaster* is designated as the early African species and *Homo erectus* is reserved for later hominins found in Asia. These differences reflect disagreements among paleoanthropologists about how many species of hominins are represented by the fossil record.

Many aspects of *Homo ergaster* and *Homo erectus* anatomy are similar. Compared with earlier hominins, both have smaller teeth, a shortened face, and projecting nasal bones. The last feature marks the first appearance of the humanlike external nose with the downward-facing nostrils. In addition, both show a significant increase in brain size compared with earlier *Homo* (*Homo habilis*). The brain size of *Homo ergaster* (860–910 cc) was about 75% the size of modern humans (1,000–2,000 cc).

Homo ergaster is primarily defined in terms of how it differs from *Homo erectus*. Relative to *Homo erectus*, *Homo ergaster* had a more rounded, higher cranium with thinner cranial bones. It also lacked a number of distinctive characters seen in *Homo erectus*. These include the supraorbital sulcus (depression behind the brow ridges), the sagittal keel (a ridge on top of the skull), and the occipital torus (a projection in the back of the skull).

Many paleoanthropologists believe that the differences between *Homo erectus* and *Homo ergaster* are too few to warrant assigning them to separate species. However, some recent analyses of the evolutionary relationships among the genus *Homo* have found that *Homo ergaster* differs from *Homo erectus* in many of the same ways that modern humans do. For this reason, other paleoanthropologists consider *Homo ergaster* the probable ancestor of later *Homo* populations (for example, *Homo sapiens*) and that *Homo erectus* represents an evolutionary dead end.

HOMO HABILIS

Homo habilis is an extinct hominin that lived in Africa between 2.3 and 1.6 million years ago. The type specimen, OH 7 (Olduvai Hominid #7), was discovered by Louis Leakey at Olduvai Gorge, Tanzania, in 1960. It consists of a mandible and two parietal (skull) bones that are 1.7 million years old. The species (literally, “handy man”) got its name from the association of the fossil with stone tools.

Homo habilis is distinguished from *Australopithecus* primarily on the basis of a larger brain, smaller molars, and aspects of the hand that support an anatomical basis for toolmaking. The brain of *Homo habilis* is estimated to have been between 500 and 710 cc (depending on the specimen). On average, it is larger than that of australopithecines but smaller than that of *Homo erectus*. The body size of *Homo habilis* has been estimated to be about 32 kg (70.5 lbs). Relative to its body size, *Homo habilis* had a large brain.

There is a great deal of variation among specimens attributed to *Homo habilis*. Some specimens show limb proportions that are similar to australopithecines (longer arms relative to legs), while others do not. It is clear, however, that *Homo habilis* was a biped. A nearly complete foot from Olduvai Gorge clearly shows characters associated with bipedal locomotion. These include the presence of both middle and longitudinal arches, the alignment of the second through fifth toes, and the enlarged big toe that is in line with, rather than opposable to, the other toes. There is some indication from the foot, however, that *Homo habilis* also spent some time in the trees. Muscle markings on the bone suggest that the foot

could be easily inverted (turned sideways), which would facilitate tree climbing.

Homo habilis was once associated with the earliest evidence for making stone tools, and paleoanthropologists considered them to be the first toolmakers. These tools consist of choppers and flakes and belong to the Oldowan tradition. The tools made by *Homo habilis* were most likely used for scavenging meat, not hunting prey. Interestingly, there is good evidence that *Homo habilis* was a major staple in the diet of large cats and other predatory animals. Therefore, rather than being “man the hunter,” *Homo habilis* was more likely “man the hunted.”

Recently, Oldowan tools that predate *Homo habilis* have been found in Ethiopia. These date to 2.5 to 2.6 million years ago. The younger tools are associated with *Australopithecus* remains (*A. garhi*). The older tools are not associated with any fossils. Based on this new evidence, it now seems possible that *Australopithecus*, rather than *Homo*, was the first hominin to make and use stone tools.

To date, indisputable *Homo habilis* fossils have not been found outside Africa. This suggests that the migration of early humans to Europe and Asia came later in human evolution. In fact, most human cultural evolution occurred in later *Homo* species. There is no clear evidence that *Homo habilis* controlled fire or buried their dead. Neither is there unequivocal evidence that *Homo habilis* was capable of vocalizing sounds recognizable as language today.

Since the original discovery of the OH 7 specimen, many more specimens attributed to *Homo habilis* have been discovered. Their remains vary quite a bit in size and shape. Based on this variation, there is debate among paleoanthropologists about whether or not the fossils attributed to *Homo habilis* represent a single species. Those who believe there is more than one species separate the fossils into *Homo habilis* and *Homo rudolfensis*.

The *Homo rudolfensis* specimens are distinguished from the *Homo habilis* specimens by having larger postcanine teeth with more complex premolar roots, larger brains, and more humanlike limb proportions (shorter arms/longer legs). The species *Homo rudolfensis* was proposed in 1986 by V. P. Alexeev for the specimen KNM ER 1470, which was originally assigned to the genus *Homo* but had not been assigned to a species. Since then, several other fossils once attributed to *Homo habilis*

or *Homo erectus* have been reassigned (by some) to *Homo rudolfensis*. For those who accept dividing *Homo habilis* into two species, there is little agreement about where in human evolutionary history *Homo rudolfensis* lies.

When *Homo habilis* was discovered, it was thought to be the ancestor to all later *Homo*. It was more humanlike than the australopithecines that had been found and less specialized than the known *Homo erectus* fossils from Asia. However, as more fossils have been discovered, the position of *Homo habilis* in the human lineage has become less clear. In the conservative interpretation (one species), it may have been the ancestor to both *Homo erectus* and *Homo ergaster*. In a less conservative interpretation (two species), *Homo habilis* may have given rise to *Homo rudolfensis* (which, in turn, gave rise to *Homo erectus/ergaster*), or it may have been an evolutionary side branch.

Toolmaking was once considered to be one of the defining characteristics of humanity. It was its association with stone tools that led paleoanthropologists to hypothesize that *Homo habilis* was more similar to modern humans than it was to australopithecines. We now know, however, that there is a diversity of toolmaking and tool-using behavior among chimpanzees. This has forced paleoanthropologists to revise their assumptions about what makes us human. Tool use can no longer be used as the criterion for a genus.

Wood and Collard claim that in order for a specimen to be classified as *Homo*, it should meet a number of criteria. These include showing greater similarity to *Homo sapiens* than to australopithecines in body size, body proportions, and in the size and shape of teeth and jaws. To be included in the genus *Homo*, a specimen should also show evidence of modern humanlike bipedal locomotion (with limited climbing capability) and of a modern humanlike extended period of growth and development. These researchers argue that *Homo habilis* (including *H. rudolfensis*) does not meet these criteria. As a result, they have suggested that it be removed from the genus *Homo* and reassigned to the genus *Australopithecus* (for example, *A. habilis*).

 HOMO SAPIENS
Age of *Homo sapiens*

The *Homo sapiens* lineage may be as old as 500,000 years. Although the oldest fossil remains only date to about 200,000 years, there is growing evidence that the *H. sapiens* lineage may be much older. Assuming that *H. neandertalensis* is its own species (and evidence for this assumption grows), then the last common ancestor of both terminal species of hominoid evolution may have lived around that time. Paleoanthropology has not yet sufficiently resolved the taxonomic status of earlier *Homo* fossils such as *H. antecessor* (more than 800,000 years from Spain), which might as well be a grade as *H. heidelbergensis*. The oldest Neandertal lived at least 250,000 years ago.

A caveat of paleoanthropology and the reconstruction of the evolutionary history of *H. sapiens* is first the decoupling of fossilized information (such as skull anatomy) from the crucial processes (sexuality, social organization, cognition, cultural evolution) in *H. sapiens* evolution. And second, the transition from archaic sapiens to modern sapiens was a continuous process.

Scenarios of Hominization

For quite a while, two contrasting models, the “out-of-Africa hypothesis” and the “multiregional hypothesis” and their modifications, dominated the discussion of the origin of *H. sapiens*. The out-of-Africa hypothesis (synonym, “Arche Noah-model,” “replacement hypothesis,” “Eve-hypothesis,” or “Lucky-Mother-hypothesis”) assumes a common origin of all modern humans in Africa and thus that their

morphological divergence of all recent human population is the result of a relatively recent differentiation. According to the “multiregional hypothesis” (or “candelabrum model”), modern human populations are derived from regional precursor populations, and Asians and Europeans are thus descendants of earlier endemic humans. The “assimilation model” tries to reconcile both diametrically opposed hypotheses, assuming a somewhat “mixture” of modern immigrants with endemic populations. Very recent findings even suggest a genetic bottleneck more than 50,000 years ago, which would even more contradict a multiregional origin of all modern human populations.

The discussions in all models are limited to the last 150,000 years of *H. sapiens* evolution.

The Fossil Record

The indisputable fossil record of *H. sapiens* actually starts in Ethiopia with the specimens Omo I and Omo II from the Kibish formation now dated at 195,000 years, followed by *H. sapiens idaltu* from Afar, Ethiopia (160,000 years), and by the remains from Border Cave, South Africa (> 100,000 years). Evidence gathered from both molecular genetics (for example, mitochondrial genes) and linguistics support an African origin of all *modern* humans. This does not necessarily imply that the origin of early *sapiens* is also found in Africa.

Short-term climatic changes in the Pleistocene led to a habitat fragmentation in Africa. The cooling effect of the climate change fragmented forests, whereas the warming effect expanded savannas. Humans, by having to react to these relatively short-term climatic alterations, learned to adapt to changing environments. This later enabled their universal dispersal (not to be confused with migration) seen in no other mammalian species. Occurrence of *H. sapiens* outside Africa is documented as being younger than 100,000 years in the Middle East (Shkul V, Israel, 90,000 years; Qafzeh IX, Israel, 90,000–100,000 years). Note that recent redating of the sites contradicts a simple succession of Neandertal and modern humans. The dispersal out into the rest of the world started more than 60,000 years ago. Humans reached Asia about 60,000 years ago, Australia around 50,000 years ago, Europe 40,000–35,000 years ago (“Cro magnon”), and America 35,000–15,000 years ago. The splitting of human ethnic groups is also documented by a similar splitting of their parasitic bacterium, *Helicobacter pylori*, into various subgroups.

Group size has become a key word in recent discussions on human evolution. Although we have no data whatsoever on the size of human groups during their dispersal, many anatomical traits indicate “genetic drift,” the fixation of randomly distributed alleles in relatively small original groups. Many traits used for ethnic distinctions have continuously escaped all functional arguments.

Anatomy of *Homo sapiens*

There is no purely anatomical-based definition of *H. sapiens* due to the difference in modern anatomy and behavior. Linnaeus distinguished between *H. diurnus*, corresponding to humans, and *H. nocturnus*, referring to the orangutan. It is the only Linnean species without a holotype of Linnaeus himself.

Diagnostic (not necessarily autapomorphic) cranial characteristics (or even better, trends) of *H. sapiens* are as follows:

- Appearance less robust than in other members of the genus *Homo*
- Reduction of tooth surface
- Tooth arcade with parabolic shape
- Rounded occipital region
- Straight forehead, therefore less prominent supra-orbital ridges (but still present in early members)
- Face orthognathous
- Orbitae more rectangular than rounded
- Deep zygomatic fossa
- Prominent chin probably due to posterior displacement of dentition indicated by the For. mentale below P_2 instead of M_1

By summarizing cranial and dental characteristics, it becomes evident that changes in mastication affect most of the above-mentioned characters. It led to reduced tooth surfaces, bite force (herewith supra-orbital ridges), and reshaping of the chin. Only after these dominant constraints onto the skull shape had been reduced was the inflation of the temporal and forebrain that led to the straight forehead and orthognathous face possible.

Diagnostic postcranial characters follow.

Body Shape

During their evolution, humans have increased in body size by approximately 150% and doubled their body weight. Most probably already in early members

of the genus *Homo* (if not earlier), a new mechanism of bipedal locomotion evolves, using a torsional mechanism of the trunk and spine in walking. Amplitudes of these torsions depend on walking speed and indicate the use of resonance mechanisms (energy saving), which at higher speeds show significant gender differences. Torsion is driven and countered by the oblique abdominal muscles. The human body forms a hyperboloid, the “waist.”

According to an idea of Weber and Weber, the legs and arms act as physical pendula during walking. Their resonance occurs at the energetically optimal speed of about 1,1 m/s—just the speed at which trunk torsion shows a relative minimum, indicating an adapted mechanical interaction between extremities and trunk. To increase the energetically optimal speed, muscles of the legs are concentrated near the trunk. The consecutive cone shape of the legs allows for great step length with short pendula and thus short swing times, leading to maximized speed. The concept was summarized under the term *inverted pendulum*. Human arms are shorter than the legs, with a more cylindrical shape and more mass distally, thus comparable pendulum length and thus dynamic properties as legs.

In walking, hip joints create about twice the force as shoulder joints, and mechanically relevant shoulder width (biglenoidal width) is double that of pelvic width (biacetabular width). More mass is concentrated in the pelvic segment than in the (air-filled: lungs) thoracic segments. Thus, the center of mass is situated in the pelvis. In the front and side views of the long trunk (in relation to our nearest primate relatives extended) with mass concentrations at its end has an asymmetric dumb bell shape. Seen from the top, the cross-sectional area of the trunk is stretched into an ellipsis instead of the more rounded shape of, for example, chimpanzees. Changes in body shape are a necessary prerequisite for an important action of hominids in throwing.

Hands

A comparison of modern human hands with those of nonhuman primates reveals features unique to humans that are related to two main functions: from power grip to precision grip, and the importance of gestures. But the basis of the manipulatory abilities that involve structural changes as well as demands for a high speed in the execution of movements should be seen more in brain development than in anatomical

changes of the hand itself. Unique human hand movements are first the ulnar opposition (moving the ulnar side toward the thumb) forming the “cup of Diogenes.” Second, the precision and squeeze grip (and many more grips) between the thumb and the fourth and fifth finger is made possible (“basket grip”). (Lucy already had a grip between the thumb and the second and third finger, according to M. Marzke.) The latter involves reorganization of the thumb muscles, especially the long flexor muscle.

Nakedness

The nakedness of humans is the result of a miniaturization of the body hairs (not loss) to a maximum size of 1–2 mm. In addition, the body hairs have lost their pigmentation. In *correlation*, the sweat glands, formerly restricted to the palm and sole in primates, are now covering the whole body, providing a maximum area of cooling by transpiration. The human ability of sweating is unique within mammals. But nakedness cannot only be seen in the context of thermoregulation but also of sexuality and postnatal development (see below). The naked skin and touch play an outstanding role in the development of emotion. The taboo of skin contact in many different recent cultures indicates the high importance of such skin contacts for the stabilization of group-adherence but also for the development of self-consciousness.

Third, nakedness together with the enormous development of hairs on the head and subcutaneous body fat has reshaped the outer appearance of humans. While subcutaneous body fat makes only 3% of body mass in primates, it makes 16% in men and up to 25% in females. Its function is related to the inflation of the brain. Normally, the brain only consumes glucose, but in the state of starvation it may cover up to 85% with ketones, which are mobilized from the fat tissue.

Already on the naked skin of chimpanzees, melanocytes (pigment-producing cells) produce melanin under UV radiation. Melanin molecules bind free radicals. Any color in humans is only due to the amount of melanin in the skin, which itself is controlled by only a few genes. They regulate the activity of an enzyme (tyrosinase) that catalyzes the first step in the biosynthesis of melanin and control the package and size of melanosomes, which finally cause the difference between the individual pigmentation.

Human colors are a subtle balance between two vitamins. The first vitamin is folate (folic acid), a

B vitamin, which is highly sensitive to sunlight. Especially during gestation, a lack of folate can cause multiple malformations. It is also indispensable for rapid mitosis such as sperm production.

In contrast, vitamin D biosynthesis needs UV radiation. Vitamin D is necessary for calcium and phosphate metabolism, for calcium uptake from the gut, and therefore for osteogenesis. In the epidermis, cholesterol is transformed into provitamin D, which is synthesized to vitamin D in the kidneys. To ensure this biosynthesis, the skin gets lighter the more northern individuals live, and even, theoretically, there is not enough sunlight for this biosynthesis beyond 50° of latitude. In the latter case, it has to be compensated by food.

Sexuality

The sexuality of *H. sapiens* differs dramatically from their closest living relatives, the chimpanzees. The subcutaneous fat tissue has increased to as much as 16%–25% of total body weight. It now shapes the human body in both sexes. The breasts of adult women are permanently developed independent of their function for lactation. In nonlactating periods, the breasts are formed by fat tissue and serve only as a sex signal. The external female genital organs are completely hidden by the major wings of the vulva as well as by pubic hair. These hairs are so different from cephalic hairs that even the lice living in the respective regions are of a different species. In contrast to chimpanzee and bonobo females, women do not signal their estrus in any way, neither by swollen anogenital skins nor by any specific secretion. The estrus of women is cryptic, and their sexual activity independent of it. Together with the unique sensibility of a naked body, and of specific erogenous zones, humans of both sexes are probably the only mammals able to orgasm, a type of brief unconsciousness (“little death” in East-Asian literature). Sexuality plays a crucial role in partnerships even beyond the period of the female reproductive age. A milestone in human evolution is the separation of sexuality from reproduction. Homosexuality as a constitutive character of all human cultures can also be considered an effect of this clear distinction.

One of the possible evolutionary consequences of the new sexuality of humans is the “liberation” of males from their sex-dominated role of achieving access to females, or defending them in harem-organized species (for example, gorilla, chimpanzee, and to a lesser

degree bonobos). Men are the only primates who cooperate to a large extent with nonrelated individuals. This male cooperativeness, together with the pleiomorphic cooperation among primate females, is one of the key structures in social organization, which preceded cultural evolution. It also allows for the first time in primate evolution a group size that is well above any biologically constrained size.

Birth

Humans have an unusually long gestation period relative to their body weight. Especially in the last 6–8 weeks, when fetal body growth ceases, the brain and subcutaneous body fat develops, of which the latter can be seen as a supply for the former in case of postnatal starvation. Human birth is unique in that the head is rotated 90° within the birth channel and the newborn is facing dorsally. The complexity of birth and the enormous risk for the mother—also unique within mammals—and for the newborn has led to the idea that assistance during birth by other women is a key factor in human evolution.

Postnatal Development and Social Behavior

Human social behavior develops from an already extremely advanced behavior of their ape sister-groups. In particular, two innate abilities are highly evolved within these groups. Apes can detect the social and emotional status of their counterpart from very small, almost nonvisible signals such as changes in body posture, and they can anticipate its implication. They can recognize other individuals as intentional agents whose attention can be shared and even manipulated. Together with a high degree of vocalization, apes have herewith evolved the highest emotional intelligence among all existing mammals.

By building upon these abilities, human evolution is characterized by a unique “sociability,” an extreme behavior directed toward immediate relatives but also psychological parents (“primary intersubjectivity”). Newborn primates have the well-known reflex of grasping at their mother, but they start very early to move on their own, and within only a few weeks or, rarely, months they are independent from their mother in regard to their locomotion and mobility. In contrast, human babies—although their gestation lasts 6–8 weeks longer than in chimpanzees—are highly retarded in their locomotory abilities. The neocortex and motor tracts descending from the cortex to the spinal cord are extremely immature at

birth, for example, axon diameter of the corticospinal tract is 10 times smaller than in adults. Descending brain control does not develop before the end of the 1st year of age. Simple spinal central pattern generators cause the action of stepping.

Babies are carried for at least the first half year and often much longer. In contrast, this extraordinary retardation in the first postnatal year allows the baby to fully concentrate on his or her mother’s actions. While being carried or lying, the child’s brain is highly active in following verbal and nonverbal indications, and long before babies can speak by themselves, they have learned to discriminate their mother’s language from other sounds. Language establishes in mother-child dyads with the communication of simple needs and desires by one- to two-word utterances. Typically, not only in humans, the way of investigating the surface and 3-D haptic properties of an object is with the lips and tongue. From haptic to optic inventory, the baby’s world changes from being purely sensomotoric to an increasingly abstract comprehension. Together with the gradual understanding of words and their meaning, abstract thinking capability is gained. It is worth mentioning that the individual constituents of humans acquired within the first 4 years cannot be remembered.

Only in its second year does the child start to develop motor abilities, including ultimately bipedal locomotion and speech by again imitating the surroundings. Note that the adult appearance of myelin is not attained up until 2 years of age. And it is only at the age of 4 that children recognize their surrounding persons as acting, thinking, and feeling in the same way as themselves, and that they develop self-consciousness (theory of mind). As a consequence, children are able to act responsibly and develop a feeling of guilt. A unique feature of humans is the extraordinarily long period of adolescence, which might even last beyond puberty. It will always remain a matter of debate whether cosmological-religious thinking was a constitutive feature of becoming human. The remains of doubtless buried people 100,000 years ago are a strong argument of the very early occurrence of such a belief in the other world. A second strong argument is the ubiquity of such a belief in human cultures. The human brain mass has increased by 3.5-fold as compared to the chimpanzee. Whereas the cerebrum increases fourfold, the brain stem remained almost unchanged. But only a closer look reveals the real changes. Some regions, for example,

the optic and acoustic area of the cortex as well as the primary motor area, are almost not enlarged. The secondary areas of association are doubled in terms of their extent, but the tertiary area of association is formed almost *de novo*, occupying about half of the cortex surface. Especially the frontal and frontobasal cortex show the major increase with respect to the temporal, parietal, and occipital regions. Accordingly, the appropriate parts of the basal ganglia are enlarged, such as the nucleus caudatus and putamen.

The inflation of the human brain is accompanied by an extremely long development of the intracortical connections, even beyond puberty. While all neurons and interneurons are present at birth, cytologically differentiated and in their proper place, they show a continuous growth until late adolescence. During postnatal growth, the thickness of the cortex doubles too among others due to the enormous growth of pyramide cells and their basal dendrites. Primary and secondary areas highly depend on multiple inputs in their postnatal development, for example, the differentiation of the visual cortex lasts at least 3 months before a baby can recognize persons clearly. It is probably the unique development of the tertiary areas that makes us humans, because their differentiation is only controlled and supported by imitation, socialization, and the deliberate, long-term learning within an intact social group. Increasing neurobiological insights have led to a profound understanding of the developmental processes in ontogenesis as well as right- and left-side hemisphere differentiation. Left-right cerebral hemispheric asymmetries exist in extant pongids and also the australopithecines, but neither the pattern nor direction is as strongly developed as the genus *Homo*.

The Evolution of Speech and Language

Vocalization is known in many different animals and mammals. In chimpanzees, more than 35 different sounds are used but in a strongly defined context. All such vocalizations are controlled by the mid-region of the brainstem. In humans, the baby's vocalizations and all sorts of sounds during fights or sex in adults are of such a type. Unique vocalizations of *H. sapiens* are crying and laughing, which are also controlled by the brainstem but initiated cortically. Vocalization should not be confused with language.

The informational content of language is exponentially higher than in vocalization. In a second, four to six syllables, each consisting of up to six consonants or

vowels, can be communicated. Production and reception of language is situated exclusively in the newly evolved associative tertiary areas of the cortex. In particular, the left hemisphere is specialized to conduct complex arbitrary actions in gesture and the vocal domain. This may have created a left hemispheric bias not only in gestural communication but also in the execution of all technical ideas.

The development of the Broca's area (the "motor speech" area) in the gyrus frontalis is intimately correlated with the evolution of language. It is unilateral in the left hemisphere. Note that a well-developed Broca's area is present in early members of *Homo* more than 1.6 million years ago, for example, KMN-ER 1470. The Wernicke's area, which is involved in the interpretation of spoken language, is not a speech center but the secondary auditory cortex and is always bilateral. The Wernicke's area of the dominant hemisphere (mostly the left side) integrates sounds more rationally, whereas that of the nondominant hemisphere "understands" the melody, which is of the highest importance in early postnatal development.

For a long time, any definition of language, as the basis of speech, has been restricted to audible sounds produced by the action of the vocal, laryngeal organs. Consequently, speech was restricted to human communication through spoken language. Only recently the possible gestural origin of language has been seriously debated. Seen in this light, for most of our evolution language would have been gestural, although more and more punctuated by (vocalizations) the production of speech phonemes. The discovery of a mirror system in primates by Rizzolatti and Arbib and its probable homology with the Broca's area in the human brain, together with the unique human ability for imitation, has strongly supported the idea that language originated in a complex system of gestures and phonemes. Articulate speech would have been completed relatively late in the evolution of *Homo*. If we accept that the Neandertals are fully capable of language, this would have occurred before both species split. It remains unclear whether humans are the only ones who used speech alone for vocalization of language and to communicate ideas and feelings. Some scientists suggest that syntax emerged only very late as a result of cultural evolution, whereas other scientists argue that language evolved exclusively in the vocal domain.

Gestural and vocal communication implies anatomical changes in the hand (see above) and vocal

system, which can be followed in ontogeny. Set free from thermoregulation due to the extension of sweat glands over the body, the upper respiratory tract changed dramatically. Motor activity in ordinary language comprises the activation of laryngeal muscles, including vocal cords, throat muscles, soft palate, tongue, jaw, and facial muscles in a highly ordered but fast sequence.

Evolution of Culture

By defining culture as the difference between learned and vested behavior of different populations, one of the keys of human evolution becomes obvious: risks are minimized and advantages are maximized by imitating successful behavior. Cultural history began when the survival of the fittest took in tow the imitation of the fittest (Eckhard Voland). This process inevitably leads to cultures and not culture—and to competition of cultures as a driving force of evolution.

HOMOSEXUALITY

Homosexuality generally refers to sexual and/or emotional attraction to members of the same sex. Homosexuality is considered to be a sexual orientation along with heterosexuality, or attraction to members of the opposite sex, and bisexuality, or the potential for attraction to members of both sexes. In addition to attraction, sexual orientation may also refer to the practice of sexual relations with members of the desired sex.

The term *homosexuality* is a relatively recent Western creation. It was initially used by European scientists who considered sexual relations among members of the same sex to be abnormal. Western views of homosexuality have had an impact on the ways in which anthropologists and other scientists have studied the topic. Changing societal attitudes in the past century have allowed for more in-depth research on homosexuality. This research, in turn, has influenced social changes.

Cross-culturally, there are diverse ways in which people perceive their attraction to members of the same sex or engage in sexual relations with them. In many cases, same-sex relations exist in addition to opposite-sex relations. They are sometimes limited to particular contexts, such as rites of passage, certain periods of life, or specific age-based relationships. In other cases, same-sex behavior is connected with gender variance, where an individual takes on the social role of the opposite sex. There are also cases where same-sex acts that would be labeled as “sex” by many Westerners do not qualify as “sex” to the local participants.

Although it exists in human societies around the world, as well as in some other animal species, homosexuality is often an issue of great contention. Its existence is considered natural or tolerable in some cultural areas, and in some cases, unions between members of the same sex are legally or socially recognized. In other locations, this is considered unnatural and is prohibited, sometimes to the extent that individuals thought to have transgressed this taboo are severely punished by imprisonment or death.

Western Notions of Homosexuality

Nineteenth-century Europe was characterized by tensions between scientific and Christian thought.

However, even scientists who tried to break from religious teachings to explain human existence and behavior were influenced by their ideological upbringing when it came to matters of sexuality. Ideas about what constitutes normal and moral sexuality are heavily influenced by religious ideology in any society, and the religious teachings in Europe at the time taught people that sexual relations between members of the same sex were immoral. Therefore, scientists rarely questioned the assumption that this behavior was abnormal and unnatural.

In addition, important research regarding human evolution during this time concerned natural selection, which is directly concerned with reproductive success and the transmittal of adaptive genes as forces of physical and behavioral change in living species. With an emerging scientific worldview that considered reproduction to be a driving human force, any behavior that appeared to deviate from it was unsurprisingly viewed as counterproductive and unhealthy in terms of the individual or group that participated in such acts.

This view of homosexuality had an impact in the field of anthropology. Physical anthropologists, concerned with human evolution, rarely considered the possibility of the existence of homosexual behavior in early human societies. In addition, early ethnographers and other observers of worldwide cultural behavior had a tendency to project Western values and ideas upon other societies. The existence of same-sex emotional attachments or sexual behavior in many areas was therefore frequently overlooked, since the evidence was not visible to Westerners who had predetermined criteria for what constituted this behavior.

In the 20th century, scientists from various disciplines, including anthropology, began to seriously question the scientific validity of this view of homosexuality. One important contribution to a more comprehensive study of homosexual behavior was the work of Alfred C. Kinsey and his research team, which included anthropologist Paul H. Gebhard. Their research brought to light a spectrum of sexual behavior among American males and females that is far more complex than the binary opposition between exclusive homosexuality and exclusive heterosexuality that existed in Western scientific and popular ideologies. Due in part to these findings, there is now a greater acknowledgment of the existence of bisexuality.

Today, there is still dispute in the scientific world regarding the causes of same-sex attraction. While some biologists continue to seek genetic sources, some cultural anthropologists, sociologists, and psychologists focus on the function and meaning of same-sex attraction and sexual relations, in particular, social structures and contexts. Some scholars in all fields disagree upon whether homosexuality is a choice or a biological predisposition. However, there is a tendency among many anthropologists to recognize an interplay between biology and culture.

These scientific disagreements are representative of the general social and ideological tensions in Western societies that have been ongoing since the 1960s. Movements for the rights of homosexuals and bisexuals have been ongoing in various Western nations. Among the rights sought by these groups are the inclusion of sexual orientation in antidiscrimination hiring policies, the right to have a same-sex partner as a beneficiary for insurance purposes, the right to adopt children, and, more recently, the right to legally recognized marriage. However, in these same nations, segments of the population are opposed to the advancement of these rights. In many cases, they perceive homosexuality and bisexuality as an affront to their religious and moral beliefs. Others cite economic reasons for their opposition to the recognition of same-sex social benefits.

Homosexuality Cross-Culturally

To avoid the pitfall of projecting Western ideas about sexuality upon the subjects of anthropological research, ethnographers examine sexual practices, including same-sex attraction and sexual relations, with reference to the cultural contexts in which they take place.

There is a growing acknowledgment that Western categories such as “homosexual,” “heterosexual,” “bisexual,” and “sexual orientation” are inadequate for explaining sexual behavior cross-culturally. While same-sex attraction and sexual behavior are frequently used as markers of identity or selfhood in the West, they are not used this way in all societies. In fact, individuals’ sexual relations with members of the same sex sometimes have no bearing on their social identities. Accordingly, references to homosexuality in anthropological literature tend to imply actual homosexual behavior rather than homosexual identity.

More is known by scholars about male than female homosexuality. Explanations for this disparity in the anthropological and historical literature are manifold. Historians point out that societies that left behind documents describing social customs and daily life, such as Ancient Greece and Rome, were male dominated. The resulting information therefore contains a focus on male activities in general.

Some ethnographers have claimed that female invisibility in general ethnographic material was due to women's confinement to the domestic sphere. Information about women's sexuality is therefore said to be difficult to obtain. Feminist anthropologists point out that most early ethnographers were men, who often conversed primarily with male informants, either by choice or because of local norms regarding male-female relations, and who focused mainly on women's reproductive and productive roles.

For both males and females, homosexual behavior is frequently associated with particular life stages. Where sexual experimentation is permitted for children and youths, it sometimes takes the form of same-sex activity. Among the Ju/'Hoansi of the Kalahari desert in Africa, for instance, the first sexual contact a child has is often with members of the same sex.

In some cases, the connection between homosexual activities and life stages are more formalized. One well-documented example is that of some Melanesian societies where boys go through a series of initiations over the course of several years. The first two initiation stages include the practice of ingesting sperm by performing fellatio on older boys. Sperm is thought to help boys become big and strong and to combat the feminizing effect of mother's milk and womb. From the third stage of initiation onward, boys contribute to the initiation of younger boys by being fellated. This practice continues until fatherhood. The boys therefore go through a bisexual period where they engage in both homosexual and heterosexual acts.

There are contexts other than initiation where homosexual contact may be limited to individuals that are differentiated by age. This was the case in Ancient Greece, where upper-class warrior men would form homosexual relations with males in their teens. Homosexual relations among men of similar ages were frowned upon. Furthermore, men were eventually expected to marry women and create families. More recently, Azande warriors of Central Africa took *boy-wives*, who would accompany them during warfare, in addition to their female wives.

Another example of age-based homosexual relationships is that of the "Mummy-Baby" game among girls and young women in Lesotho, South Africa. This is a form of relationship where young women become "mummies" to younger "babies." These relationships resemble courting relationships, with the "mummy" buying gifts for the "baby" and the presence of emotional bonds and sensual affection. These bonds occasionally last into adulthood.

An important aspect of various homosexual activities cross-culturally, including the examples described above, is that they often coexist with or are a precursor to heterosexual activities. The Western definition of homosexuality then becomes limiting, since it implies exclusive homosexual activity. Furthermore, this aspect of homosexual behavior calls into question the assumption that homosexual behavior is a maladaptive force that preempts reproduction.

Another aspect of many of the homosexual activities documented in the ethnographic literature is that they are sometimes not classified as sex by local participants. Where the cultural definition of sex is limited to coitus and is perceived as a reproductive act by nature, acts such as same-sex genital-genital rubbing, digital-genital, oral-genital, digital-anal, or genital-anal contact may not be considered to be sex. It is partly for this reason that homosexual behavior has little bearing on the identity of the participants.

There are also examples of homosexual behavior that is related to identity, especially gender identity. Where sexual behavior contributes to the construction of gender identity or where it is an important component, engaging in homosexual behavior may be an indicator of an alternate gender identity.

One example is that of several Latin American societies where there is a strong male-female dichotomy. The act of sexual penetration comes to symbolize a power relationship, where the male penetrator possesses the penetrated female. This symbolism extends to homosexual penetration. The man who penetrates another sexually maintains his status as an active male, whereas he who allows himself to be penetrated assumes the status of a passive "non-male." Although he is not considered to be female, the passive "non-male" is expected to take on other aspects of femininity, such as dress and demeanor. In some cases, he may ingest female hormones to modify his body. In this example, it is not the act of homosexual behavior itself that alters the gender identity of the participants, since the active partner

maintains his social status. Rather, it is the act of being penetrated that alters one's identity.

Another example of homosexual behavior that is associated with a change in gender identity is that of Native North American gender variants. A gender variant is one who assumes the social role of the opposite sex. While more documentation is available for male gender variants, or biological males who take on female social roles, female gender variants do exist. For both male and female gender variants, there is a range of the degree to which they take on the characteristics of the other sex. In some cases, they may take on some of these characteristics while keeping some that are appropriate to their biological sex, whereas in other cases, they may take on the entire range of characteristics of the other sex.

In cases where the gender variant takes on the entire set of characteristics that are socially ascribed to the opposite sex, he or she will also practice sexual relations with members of the appropriate sex as defined by his or her social role. Therefore, the female gender variant in this situation will engage in sexual practices with women, since she is socially a male. In cases where there is a combination of gendered traits that are adopted, the gender variant may or may not engage in homosexual activities. In this example, homosexual behavior does not lead to an alternate social identity. It is, instead, a product or component of it.

Homosexual behavior is not always limited to particular life stages or contexts of gender variance. There are recorded cases where long-term same-sex arrangements were socially validated and recognized. One prominent example is that of formal lesbian relationships among Azande women. In some cases, these relationships were formed among cowives within polygynous households, where two or more women were married to one man.

There are societies where homosexual behavior of any kind is forbidden and the transgression of this norm can lead to heavy legal or social penalties. This is often the case in nations that have a strong Judeo-Christian or Muslim influence, since the various religious systems encompassed by these general categories tend to have an unfavorable view of homosexuality. For many participants in these religious systems, homosexual behavior goes against basic moral values.

Even within various religious organizations, there is disagreement about the acceptance of homosexual

and bisexual identity and behavior. Recent events worldwide, such as transnational movements to appropriate the right to marry for same-sex couples, have created divisions within the Anglican Church, for example.

Various societies where homosexual behavior is considered to be immoral also differ with respect to the social sanctions leveled against transgressors. In some cases, social stigma may result, whereas some nations have legal penalties for individuals thought to engage in homosexual activities. These penalties range from fines to imprisonment to death.

Homosexuality and the Modern Human Experience

Regardless of the various social perceptions of homosexual behavior that exist in the world, people continue to participate in same-sex erotic activities. Although there is enormous variation in the way these activities are defined and explained cross-culturally, there have been waves of large-scale cultural diffusion contributing to the spread of Western ideas about homosexuality.

Colonization by Europeans in the past few centuries initially spread Christian ideas about sexuality and the belief that homosexual acts are immoral to parts of the world where homosexuality may have had a positive or neutral value in previous times. More recently, globalization has propagated other ideas about homosexuality throughout the non-Western world, including former colonies. Some of these ideas stand in contrast to the belief systems that were previously instilled through colonization, while others support them.

While movements for the rights of homosexuals, bisexuals, and other categories of people who are often connected with them, such as transsexuals, are assuming transnational proportions, religious and political groups that are opposed to these rights are doing the same. Given this current circulation of ideas, it is difficult to assess the actual extent of homosexual behavior around the world. Homosexuality becomes a delicate topic of discussion for many anthropological informants.

The only thing that can be stated with certainty is that homosexuality is a part of the human experience and that human cultures vary widely in the ways in which they interpret and give meaning to this behavior. Indeed, there is no unique way to understand

homosexual behavior, and it may be the case that there will always be a struggle between those who consider it as a form of deviance and those who perceive it as a positive aspect of human relations.

HOPI INDIANS

Hopi, which means the “Peaceful People,” have lived in the Black Mesa region of the Colorado Plateau since their emergence into this, the fourth world. Living in this world is therefore referred to as the “Fourth Way of Life” and is reflected in the fact that when Maa’saw offered groups of people ears of corn, the Hopi were given a short, blue ear. After a period of clan migrations, the People settled on the mesas, where they still reside today and follow the Hopi way—*Hopivötskwamî*—the Hopi Path of Life, to preserve the good things of Hopi life. In Hopi philosophy, all life is a journey, and each group of people has a path that should be followed with humility, cooperation, and respect. According to Emory Sekaquaptewa, *Hopivötskwamî* includes every part of Hopi society and culture and is a comprehensive philosophy that touches the lives of Hopi on a daily basis. It gives Hopi a strong sense of security in an often-troubled world by relating the past to the present and ensuring cooperation with supernaturals, who provide rain, abundant crops, health, and well-being.

The Hopi speak a Uto-Aztecan language related to O’odham (Pima) and Ningwi (Southern Paiute), called Hopiikwa. This language has dialectical difference among the communities. Hopi population has grown throughout the 20th century, from a low of about 2,200 in 1900. In 1995, the Hopi numbered 7,785 tribal members, with a labor force of 2,170. A highly educated group, 63% are high school graduates. Many Hopi work in Southwestern urban areas, returning frequently to Hopi to fulfill social and religious obligations. It is in this way and through oral tradition that the Hopis transmit the essential parts of their history and the perspectives needed to follow Hopivötskwani.

A basic tenet of Hopi philosophy is that humans live in harmony with nature. In their view, religion permeates all aspects of an inextricably interwoven life. Nature, gods, spirits, animals, plants, the land, and the people are one in an unchangeable relationship. This philosophy is community based, and each of the 13 Hopi villages, located in the mesa and canyon country of northern Arizona in Coconino and Navajo counties, is ritually considered to be the center of the world, and each respects the others’ independence. The Hopi belief that mankind evolved during life in four underground worlds, with a final emergence of the Hopi in the Grand Canyon, through a *sipapu* (place of entry to the present world), Hopi villages in their layout and architecture serve as living reminders of their emergence.

Hopi villages are located on three mesas, extending south from the southern escarpment of Black Mesa (First Mesa: Walpi, Sichomovi, and Tewa-speaking Hano, with Polacca located at the mesa base; Second Mesa: Shipaulovi, Mishongnovi, and Shungopavi; Third Mesa: Old Oraibi, Hotevilla, Bacabi, Kykotsmovi/New Oraibi) and 40 miles to the west, along the Moencopi Wash (Lower and Upper Moencopi). Each village consists of a series of multistoried, terraced structures, containing a number of living units, arranged in long rows or irregularly around a central plaza, the *kisoni*. The *kihu*, the individual matrilineal/matrilocal residence, is a rectangular structure constructed of sandstone and adobe mortar, with a roof of timber, cedar bark, and adobe mud. Today, such traditional houses are supplemented by the Department of Housing and Urban Development (HUD) concrete block housing below the mesa tops, especially in new communities, such as Polacca and Kykotsmovi. There are larger houses with hipped

roofs, electricity, and indoor plumbing. Some of the more traditional villages have decided not to introduce such evidence of the outside world into their religious centers on the mesa tops.

Each village is situated around *kivas*, semi-subterranean religious structures built in the form of a rectangular keyhole, located in the plaza, in the broad street, or at the ends of the house-blocks. The architecture of the kiva is highly symbolic of Hopi origins, and the sipapu is represented in each as an opening in the floor. The ladders that stand against the doorless walls or extended above the entrance into the kiva remind Hopis of the trees they climbed during their emergence to this world. It is predominantly a man's space. The sipapu and kivas are the centers of each village, and the plazas and houses are built around them.

The central plaza of each village is the focal point for a complex ritual calendar that is basically composed of two sections. These are divided by the summer and winter solstices, with priestly ceremonies involving the Snake, Antelope, Wuwutsim (ceremonies of the four men's societies), and women's societies in the summer and fall and *kachina* (*katsina*) ceremonies in the winter and spring. *Niman* (Home Dance), which takes place in July, is the last *katsina* dance of the cycle. At the end of this daylong ceremony, the *katsinam* return to their spiritual home at the San Francisco Peaks, Kisiau, and Waynemui. "Social Dances" include the Buffalo Dance, a winter ceremony that deals with hunting and immediately follows the winter solstice, and the Butterfly Dance, which immediately follows the summer solstice and is associated with agriculture. Hopi rituals constitute communication and exchanges (prayers and offerings) between the world of the living and the world of the spirits, to the mutual benefit of both. Many ceremonies seek to maintain harmony with nature, enhance prospects for good health and a long, happy life, or are supplications for rain. Through the rituals that include dancing, Hopi celebrate the renewal of life, their history, and their spiritual connection with their ancestors.

Much of Hopi religion is concerned with fertility and sustaining life. In this regard, corn is an exceedingly important symbol. In fact, corn provides Hopi with a central metaphor: how to survive and grow in a difficult world. Hopi ceremonies are founded in an emergence text and clan traditions. This sacred knowledge (*wiimi*) is given expression in prayer

offerings and ritual. Only those who have been initiated into the religious societies or members of the clan who have access to certain bodies of knowledge and the sacred objects that embody it are allowed to use it. The Hopi have been extremely vigilant in protecting this powerful knowledge so that it will not be used inappropriately by those without the right and sacred protections to use it properly.

All of Hopi land is bounded on four quarters by holy mountains. Within this area are sacred shrine, trails, pictographs that mark the activities of ancestors, and places from which Hopis gather sustenance. This is the landscape in which the Hopi reside in harmony with spirits contacted through sacred rituals performed to ensure prosperity and the proper functioning of Hopivotkwani. It is in this area that the Hopi welcomed the Tewa and let them establish the village of Hano on First Mesa in 1775. Today, the people of Hano are tied to the Hopi through their social and ceremonial system in complex ways that allow each to retain their independence. Supernaturals have designated the land on which Hopis live and over which their ancestors have walked as sacred. It cannot be bought or sold, and Hopis cannot give it away, for they are entrusted with preserving it. The Hopi have an extensive body of oral tradition that underlies and reinforces this belief.

The Hopi are the westernmost Puebloan people. Their reservation, a subset of their sacred land, was established by executive order on December 16, 1882, with an area of 2.6 million acres. They were surrounded by the Navajo reservation. About 300 Navajos lived within the boundaries at the time, and more moved in over the years, settling closer and closer to the villages. In 1936, the Bureau of Indian Affairs (BIA) divided the Hopi and Navajo reservations into 18 land management and grazing units, reserving for the Hopi only one, District 6, a mere one fifth of their original allocation. This action and later court decisions establishing a joint use area in 1962 have meant the Hopi have had to spend a great deal of time regaining control of their original lands. The Navajo-Hopi Land Act Settlement (1974) led to the partitioning of the land. Today, Hopi land covers over 1,561,213 acres and is bounded on four sides by the Navajo reservation. Land issues have continued up to the present day.

Hopi social structure is a complex of important interlocking social groups. Some of these are named

and some unnamed. Named groups include villages, clans, and religious societies; unnamed groups are households, lineages, and phratries. Kinship and relatives are the most important part of Hopi social organization and form its core. Phratries (groups of clans that emerged together from the underworld or migrated together) and clans are exogamous and carry obligations and responsibilities for members. Clans consist of multiple families who trace their origin to a common ancestor. Membership is traced through a mother, and women inherit property through their mothers' clans. Originally, there were approximately 75 clans, of which 34 still exist, extended throughout the current villages. Clan members must take care of each other and treat relatives with great respect. While the father's relatives are important (they care for a mother after a child's birth and name the child), an individual's primary responsibilities are to the natal clan.

Each clan has its own village, which documents how they came to be and recounts their migrations to the Hopi mesas. The first clans that came from the ancestral Pueblo territories to the north and east have seniority. The Water clan and others came from the south. Clans came to each village one at a time and were admitted based on negotiations and commitments for certain ceremonial and secular services to the people. There is a prime clan in each village, and others cluster around this social group in arrangements of dependency and support. Each clan is important, however, since it protects ritual knowledge, hosts ceremonies, and protects sacred objects. Each clan has critical responsibilities to ensure that it functions in accordance with Hopivötskwamî. Clan membership requires specific duties be performed and ceremonial offices be fulfilled. Flexibility is inherent in the system to take advantage of environment opportunities or overcome demographic problems. Satellite clans may shift from one grouping to another, based on changing conditions and opportunities. The prime clan has the responsibility to make reassignments of any ceremonial office or duty not being carried out. Of primary importance is that continuity is ensured.

Hopi is a federally recognized tribe with a BIA agency at Keams Canyon, 32 miles east of First Mesa, even though each village considers itself an autonomous political and social entity. The Hopi are also governed separately in each village by traditional means, based on social and religious structures. The

Hopi Tribal Council was established by constitution in 1936, under the 1934 Indian Reorganization Act; prior to this, the separate villages did not constitute a single political entity or "tribe." After lying dormant for a number of years, it was reorganized in the mid-1950s. Today, the government is composed of a chairman and vice-chairman, each serving for 4 years, and council members with 2-year terms. Representatives from four districts (First Mesa, Second Mesa, Third Mesa, and Moenkopi District) meet quarterly at the tribal headquarters in Kykotsmovi.

The Hopi are noted traditionalists who have spent a great deal of time and effort preserving their way of life on their isolated lands and deciding after careful reflection which part of the global economy and popular culture to embrace. This does not mean that they are unsophisticated about television, cellular phones, or VCRs. They have simply considered carefully which parts of American culture and society work for them. Housing has also changed, with many families living at the base of the mesas in order to make it easier for children to attend schools, obtain electricity, and to drive to work. The traditional villages are still important, however, and serve as the sites of social and religious integration.

The Hopi were traditionally agriculturalists, hunters, and shepherders, supplemented by trade, and while farming has declined, many families still plant corn, beans, squash, and tobacco on clan lands every year. Many still raise a small number of cattle and sheep. Gardens near the villages are tended by women; men care for cornfields and livestock farther away. The Hopis also engage in wage work, both on and off the reservation, in skilled and professional jobs. Many Hopi earn their living as artists, specializing in silver and gold jewelry, pottery, carving, painting, and basketry. Producing beauty is a long-standing tradition, and there has been a ready market in Anglo-American society since the 1880s for both utilitarian and fine art. Many Hopi artists are internationally famous, and different villages are noted for particular art forms. The Hopi also produce significant pieces for themselves, for trade with other Indian communities, and for kinship and ritual purposes. Fathers and uncles produce kachina dolls (*tithu*) for children, a groom produces a special dress for a bride, and a bride's family supplies baskets or pottery to the groom's family, cementing all important social relationships.

The tribal government has undertaken several economic development projects as the Hopi economy changed from subsistence activities to wage work. While the Hopi have few natural resources that an industrial society values, in 1966, the tribal council allowed the Peabody Coal Company to strip-mine 25,000 acres on Black Mesa. There was great opposition to this lease, however, in many sectors of Hopi society. The Hopi tribe also engages in housing construction, industrial parks, retail facilities, and tourism. Hopi are employed by the mines, the government, and in service and tourism industries. Like other rural areas, unemployment is unfortunately high: 27% in 1995.

The Hopi have six elementary, one middle, and one high school on the reservation. They have a substantial scholarship program to help members attend accredited colleges, and an adult vocational training program. There are two health clinics and two full-service hospitals in Keams Canyon and Tuba City. Residents are served by a weekly and a biweekly newspaper. The Hopi tribe has recently established a Hopi Water Utility Authority. Arizona Public Service Company provides electricity to most villages, and water and sewage services are obtained from the U.S. Public Health Service and the Navajo Tribal Utility Authority. There is also an airport, laundromats, gasoline stations, and small retail stores. Residents still need to travel to Winslow, Tuba City, or Window Rock to shop at large grocery stores.

The Hopi government operates a very active cultural preservation office, which regulates archaeological activity, protects sacred sites, and conducts projects of interest to tribal members. Hopis are actively working on language preservation through the development of a Hopi dictionary and courses in the Hopi high school. On Second Mesa, they run a small museum and an arts-and-crafts establishment. Tourism and the sale of art fulfill economic functions and serve as a source of identity.

The Hopi way of life is a living tradition that shapes every aspect of their lives. The preservation of this way of life and the protection of sacred place is paramount.

HORTICULTURE

For most of the 20th century, anthropologists were keen typologists, preferring to categorize and classify the diversity of social and cultural phenomena they encountered. The diverse ways in which people engaged in production to satisfy their subsistence needs fell within five broad categories. One of these adaptive strategies is known as *horticulture*. Horticultural production is found throughout the world in a wide variety of climatic and geographical circumstances. To some extent, the more common association of horticultural production to tropical climatic zones skews our understanding of this adaptive strategy.

The general, defining characteristics of this form of production include a nonintensive use of land and labor, simple technology, varying periods of fallow, and human labor as the only means of working and fertilizing the land. More specifically, horticultural activity involves a preliminary clearing and burning of vegetation in an area determined by the group to be ready for production. Following a season of growth and harvest, the area is abandoned and left to regenerate until needed again. This is known as *fallow* or *shifting cultivation*. The period of fallow can range from 2 to 25 years, depending upon the location and fertility of the soils. When burned and the vegetation reduced to ash and charcoal, the area is cleared of debris and readied for planting. Apart from the use of adzes, machetes, and fire in the preparation of land for planting, the simple digging stick or hoe is the primary tool of production.

Once cleared, the horticultural plot is planted with suitable cultigens, depending upon climatic and soil conditions. Generally, horticultural production is associated with tubers, such as yams, potato, taro, and manioc, or seed production, including cultigens such as maize, beans, and squash. While all populations plant a variety of food crops in their cleared plots, there is always a dominant cultigen that people regard as their staple and around which much social and ritual activity revolves.

Apart from periodic bursts of activity during a growing season, depending upon the needs of the cultigen and the conditions in which it has to grow, the plot is maintained with little effort, leaving the group plenty of time for other activities. As in all other forms of subsistence, horticulturalists engage in other activities to secure food. Hunting and gathering available foodstuffs are often a daily part of people's lives, as is the raising of domesticated animals, such as pigs, chickens, goats, and sheep. Harvest brings on a new urgency as the crops are removed from the ground and people celebrate the results of their labor. Soon after, other areas are identified for clearing and a new cycle begins of clearing, burning, planting, growth, and harvest.

Other terms used for horticultural production are *slash-and-burn*, *swidden*, or *shifting cultivation*. *Slash-and-burn* refers to the seasonal clearing of new

ground, emphasizing how vital the burning of vegetation is to the fertilization of the land. *Slash-and-burn* methodology also enables a relatively labor-free means of clearing. Swidden refers to the characteristically small tropical forest clearings found in South America, Melanesia, the Pacific, Indonesia, South Asia, and Africa. Although horticultural production is capable of supporting large populations, there is a tendency for these to be dispersed into smaller village groups, who in some areas relocate their villages to remain close to

the newly cleared garden plots, hence their "shifting" strategies as a form of adaptation.

HOWELL, FRANCIS CLARK (1925–)

Francis Clark Howell, better known as Clark Howell, is one of the most influential and respected physical anthropologists in North America today. Howell pioneered an integrative multidisciplinary approach to

the study of human origins that combines vertebrate paleontology, evolutionary biology, geology, ecology, and prehistoric archeology. This comprehensive Howellian approach is now the standard against which all early hominid excavations are measured. Howell is distinguished by his five decades of continuous work and contributions to the field of paleoanthropology. He has published prolifically, organized and participated in important conferences, and has mentored numerous students such as Leslie Freeman, Geoffrey Pope, and Don Johanson. He is genial, personally warm, and renowned for his encyclopedic mind. He was one of the first physical anthropologists to adopt gender neutral terms, something he attributes to his wife's (Betty's) influence.

Born in Kansas City, Missouri, Howell was raised on a farm where he developed an interest in natural history that influenced him throughout the rest of his life. After serving as a signalman in the U.S. Navy during World War II, he studied anthropology and related geological and biological sciences at the University of Chicago, where he completed his bachelor's, master's, and doctorate degrees in a record 6 years under the direction of Sherwood Washburn. In 1955, after teaching in the department of anatomy, School of Medicine, at Washington University in St. Louis, Missouri, Howell joined the faculty at the University of Chicago, where he became chairperson of the anthropology department in 1966. In 1970 he moved to the University of California, Berkeley, where he is currently professor emeritus, directing the Laboratory for Human Studies.

In 1957–1958 Howell conducted excavations in Isimilia, Tanzania. His most notable accomplishments include initiating and directing the Torralba (1961–1963) and Ambrona (1980–1983) research projects in Spain, where he brought his integrated approach to bear on excavations of Acheulian sites. Howell's leadership of the U.S. contingent of the International Omo Research Expedition to southern Ethiopia between 1966 and 1973 was another important achievement. He organized and directed the multidisciplinary studies conducted by the group. Besides providing an exemplary record of excavation and data collection, this expedition documented that australopithecines existed 4 million years ago, instead of the 2 million years that had been previously thought. In addition, Howell brought back two mandibles, including a massive one that validated Phillip Tobias's and Ron Clarke's reconstruction of such a massive mandible for the OHS (*Zinjanthropus*)

cranium. More recently in 1988–1989, Howell was codirector of the Yarımburgaz Research Project of cave excavations in Turkey.

Howell has been active in professional organizations, serving as vice president of the American Association of Physical Anthropologists and as a member of the executive board of the American Anthropological Association, among others. He was elected to the National Academy of Sciences in 1972 and to the French Academy of Science in 1990. In 1975 Howell led the first paleoanthropological delegation from the United States to the People's Republic of China. This was followed in 1987–1988 by a study tour of Miocene, Pliocene-Pleistocene fossiliferous localities and fossil vertebrates in Yunman, China. In addition to his numerous scientific publications, Howell published a popular book, *Early Man*, which was widely read and influential and was also involved in a television special, "Man-Hunters." Howell's influence continues through his cochairing the science and grants committee of the L. S. B. Leakey Foundation.

HOWLING MONKEYS

Howling monkeys are a group of New World Monkeys (NWM) belonging to the subfamily Alouattinae and genus *Alouatta*. There are eight species of howling monkeys—the red-handed howler (*Alouatta belzebul*), black-and-gold howler (*A. caraya*), Coiba Island howler (*A. coibensis*), brown howler (*A. fusca*), mantled howler (*A. palliata*), black howler (*A. pigra*), red howler (*A. seniculus*), and the Bolivian red howler (*A. sara*). Howling monkeys are so named because of the loud territorial calls they

Source: © Tom Brakefield/CORBIS.

make. The vocalizations are created by air being forced through a specialized, hollow hyoid bone. The resonance results in a loud, howling-like roar that can be heard up to 5 kilometers away.

Howling monkeys are diurnal and live in a variety of forests in Central and South America. They can be found in tropical rain forests, secondary forests, montane forests, llanos forests, and dry deciduous forests. Males and females are sexually dimorphic, meaning that the males are bigger (4.5 kg–11.4 kg) than the females (3.1 kg–7.6 kg). Some species are also sexually dichromatic, with males and females having different color coats. Other species exhibit no obvious differences in hair color.

Howling monkeys have forelimbs and hindlimbs that are almost equal in length. They are arboreal and quadrupedal, moving slowly through the canopy. Howlers have prehensile tails that are used for suspensory behaviors, especially when feeding. The tail acts as a fifth limb, allowing howlers access to foods they normally might not be able to exploit without the help of the grasping tail. Their thumbs are almost absent, and thus they hold objects between their second and third fingers. This phenomenon is called “schizodactyly,” which literally means “between fingers.”

Howling monkeys are one of the most folivorous NWMs. They feed on leaves (both young and mature), fruits, flowers, buds, and petioles (stems that support the blades of a leaf). Since the majority of their diet is made up of leaves, howling monkeys have a special sacculated stomach in which the high amounts of cellulose in leaves are digested. Howlers also have large mandibles and specialized teeth indicative of their folivorous diet. They have shearing and grinding crests on their upper molars, which help them process the fibrous plant materials they consume.

Compared to other NWMs, howling monkeys have relatively small home ranges (4 ha–20 ha), with day ranges sometimes as short as 100 m. This could be due to their leafy diet, which does not afford them a lot of energy for traveling long distances. Howlers also spend a lot of time resting, possibly to conserve energy.

The social organization of howling monkeys varies by species. Red-handed howlers live in one male-multifemale groups, while mantled howlers have multimale-multifemale groups. The black-and-gold, Coiba Island, brown, black, red Bolivian, and red howlers have variable social structures. Some species

consist of one male-multifemale and/or multimale-multifemale groups. The status of howling monkeys in the wild is variable. The International Union for Conservation of Nature and Natural Resources lists five species as Lower Risk, one species as Vulnerable, and two species at Critically Endangered due to habitat loss.

HRDLICKA, ALES (1869–1943)

American physical anthropologist Ales Hrdlicka is most widely known for theories concerning *Homo Neandertalensis* and New World migrations. Born in Bohemia in 1869, Hrdlicka entered the United States in 1882. Similar to other immigrants, he held a nominal job as a cigar maker while attending night school. Encouraged to seek a profession in the medical field, Hrdlicka entered the Eclectic Medical College of New York City. After graduating in 1882, he entered the New York Homeopathic College, whereby he graduated in 1894. Hrdlicka's internship in the New York Homeopathic Hospital for the Insane resulted in an academic publication (1895), possibly resulting in the opportunity for research at the College of Physicians and Surgeons in 1897 to 1898. Returning to Europe, Hrdlicka went to Paris, France, to study anthropology under the auspices of L. P. Manouvrier. After completing his studies, he returned to the United States as an associate for the New York Pathological Institute. Moreover, he was the director of physical anthropology for the American Museum of Natural History in 1899 and curator of the physical anthropology collection at the Smithsonian Institution in 1910.

Ales Hrdlicka's contribution to physical anthropology was extensive. Inquiries into the taxonomical relationship between *Homo Neandertalensis* and *Homo sapiens* resulted in several publications, most of which entailed critical analysis of the evidence within a logical framework. In viewing *Homo sapiens*' development as being a product solely in the Old World, Hrdlicka developed a theory of migration that could account for the populating of the New World. Besides his achievements in these academic areas, he established the American Journal of Physical Anthropology (1918) and the American Association of Physical Anthropologists (1928). Always open-minded, Hrdlicka continued his point of inquiry throughout his professional career, stressing morphological variation of our species, phenotypic expressions among all populations within the Americas, and the evaluation of hominid taxonomical structures in light of new evidence. These qualities can be seen throughout his life and anthropological career.

Contributions and Perspectives

Taxonomical structures and origin of descent have become controversial and uncertain. Questions concerning essential morphological features and shared characteristics have compounded an already complex problem. In this manner, the exact nature and placement of *Homo Neandertalensis* in relation to *Homo sapiens* is a point of critical inquiry. Hrdlicka came to view *Homo Neandertalensis* as a continuous branch in human evolution, unlike the commonly held view that it is an extinct ancestor from *Homo sapiens*. This view was imparted to his definition of Neandertal man within a continuous evolutionary framework.

Hrdlicka defined Neandertal man as being *the man and the period of the Mousterian culture* (his italics). This phase can be found in multiple encampments found in Europe, Crimea, and parts of North Africa and Asia Minor. Primarily associated with the Mousterian culture, this phase or "Mousterian man" cannot be strictly defined by the fauna that was prevalent during that period of time. Rather, Mousterian Man existed during the last part of the interglacial and well into the final glacial period. According to Hrdlicka, Mousterian man is a transitional phase between Acheulean man and Aurignacian man. This can be seen in the sequences of culture depicted among them. Perhaps dictated by the

ebbing then advancing glacial periods, cultural evidences could be found in both open and sheltered sites. From the Chellean to the Aurignacian, the same occupational behavior can be seen: the utilization or reutilization of sites by the previously held distinct phases of Acheulean, Mousterian, and Aurignacian man.

To further this continuity, Hrdlicka illustrated the cultural similarities shared among these phases of humankind. Thus, accordingly, each phase is characterized as being chiefly hunters with association with the use of fire. Bones and other refuse can be found in the area of inhabited caves. Agriculture, domesticated animals, and food storage are unknown. Clothing was probably made from animal skins, as suggested by the evidence of tools (for example, stone and bone). In this manner, the sequence of industries is seen as being progressive, whereby the Mousterian industry can be viewed as being transitional phase between Acheulean man and Aurignacian man. Without any significant and abrupt advancement between phases, the development of art that is associated with Aurignacian man cannot be the sole factor in the segmenting of these phases. Varying artistic expressions, though not pictorial, can be found in the Mousterian culture. Any discontinuity or advancements can be viewed as being accumulative and localized. In fact, evidence suggests that sporadic discontinuity between phases (for example, when the earliest Aurignacian does not follow Mousterian) discounts a total collapse or cultural extinction.

The greatest distinction in the Neandertal phase from any other phase is within the morphological features exhibited by Mousterian man. According to Hrdlicka, the Mousterian period should be arranged in three stages, inferior, middle, and superior. However, the act of stereotyping this phase by specimen Spy No. 1 and La Chapelle had far removed the possibilities of a prototype Mousterian man, perhaps casting shadows of doubt on specimens such as the Gibraltar skull, Banolas jaw, and Ehringsdorf jaw. Traditionally, the classical description of the Neandertal includes moderate stature with stocky build. The skull is oblong, with a low forehead and prominent supraorbital torus. The facial region exhibits both low vault and forehead, a large nose, full maxilla, and a heavy mandible with large teeth. These characteristics, including variations, suggested to Hrdlicka that Mousterian or Neandertal man was a transitional phase to modern *Homo*. Although it is easy

enough to compare and contrast the morphological subtlety between these forms, Hrdlicka suggests that the cranial capacity, including variation, is comparable to both the Aurignacian and present primitive man. Furthermore, as archaeological evidence suggests, *Homo sapiens* always followed the Mousterian phase, never coexisting or preceding. In Hrdlicka's evaluation, some of the morphological features of Neandertal present in primitive *Homo* seem to suggest a branching lineal progression from one form to another.

Questions concerning the placement of this form within an evolutionary taxonomical structure are a source of discussion. Similar to controversies surrounding other hominid forms, the lack of sufficient number of specimens and gaps in the evolutionary ladder, including cultural aspects, will always be a point of critical inquiry. Though not deterred or dejected, anthropology does have the ability to reconstruct the past based on physical evidence with rational speculation. There are three carefully examined theories about the fate of the Neandertal. The first suggests that Neandertal underwent extinction and was replaced by *Homo sapiens*. The second theory states that Neandertal coexisted with *Homo sapiens* and eventually formed a hybrid. The third theory states that Neandertal evolved into *Homo sapiens*. Hrdlicka was in favor of the third theory. Based on the archaeological evidence, weather patterns based on periods of glaciation, the adaptive capabilities of *Homo* (cultural), reduction of morphological features, and variation, Hrdlicka supported the basis of his conclusion. Today, DNA analysis suggests that Neandertal phase had diverged (branched) around 650,000 years ago, only to be displaced by *Homo sapiens*. Vying for the same ecological niche, *Homo sapiens* probably had out-competed Neandertals for valuable resources and reproductive power, all of which translates into extinction. This process had eventually contributed to their extinction. Although Hrdlicka's view still resonates with some anthropologists, Neandertal represents an extinct phase in human evolution.

Besides his interest in hominid evolution, Hrdlicka was also known for his evaluation of the American aborigines. According to Hrdlicka, the evidence suggests that the Americas were never a place of origin; thus, the aboriginal population must have migrated to the Americas. The following characteristics mark them as having a common ancestor: color of skin

(from yellowish to solid brown), straight black hair, mental characteristics, low heartbeat rate, dark-brown eye color, well-developed nasal bridge and large malar regions, and moderate-length neck, hands, and feet. Considering the phenotypic expressions exhibited by aboriginal populations, the placement of their origin points to the inhabitants of the Tibetans, Upper Yenisei natives, and some northeastern Asiatic populations. Whether by land, ice, or water, this population came to the North American continent via the Bering Strait during the Holocene period. In a short period of time, this population spread rapidly and underwent differentiation. In its totality, the aboriginal population represents one *homotype*, with variation on both the phenotypic and cultural level.

Against the odds, Ales Hrdlicka attained the American dream. Intelligence, hard work, and perseverance created the foundations for the possibilities of his future contributions. Considering all forms of evidence (for example, physical specimens and cultural artifacts), Hrdlicka presented a logical hypothesis concerning the sequence of hominid phylogeny. Furthermore, his analysis of the populating of the New World had contributed to the overall understanding of natural history in the Americas. Though today, his understanding would draw severe criticism, and perhaps sociopolitical sanctions, his contributions, nevertheless, increase the awareness of the unity of our species in its origin and development.

Huari represents one of the few civilizations that were actually lost from historic records only to be rediscovered by archaeologists centuries later. Since its rediscovery in the 1940s, it has become almost synonymous with the era known as the Middle Horizon (AD 550–900), though deep excavations at several large sites suggest the civilization has roots as early as about AD 400. From its home in the central highlands of Peru, Huari spread out to control an empire that spanned two thirds of the Peruvian Andes, stretching from the Moquegua Valley in the south to the Cajamarca Valley in the north.

Max Uhle found remnants of the Huari civilization in his studies of Andean archaeology at the turn of the 20th century. The ceramic materials bore designs similar to those found on the stone carvings at the site of Tiwanaku. Hence, Huari materials were initially classified as “Coast Tiahuanaco.” Through a series of discoveries, excavations, and publications in the late 1940s and 1950s, archaeologists came to recognize two separate prehistoric states: Huari to the north and Tiwanaku to the south.

The capital site of the Huari Empire may represent the first truly urban setting in South America. The core of the site, located near Ayacucho, Peru, contains approximately 400 hectares of dense architectural remains and refuse, surrounded by a less dense periphery. Walls of cut masonry, rubble, and rounded cobbles may have stood as high as four stories in some places. Buildings were organized as interconnecting sets of narrow rooms, surrounding open plazas that created an overall pattern of large, square cells. Interspersed with the square architecture are specialized and religious structures consisting of platforms, large D-shaped buildings (10 m diameter), and large stone slab tombs. Canals may have been used to supply the site with water.

The city of Huari does not exhibit signs of urban planning, but associated settlements in other areas show intense organization. At sites such as Pikillacta, Jargampata, and Viracochapampa, the Huari used units of square plazas, narrow rooms, and platform mounds to create large repeating units that could be used for residential, administrative, ritual, and storage purposes, depending on the specific organization of the individual units. These compounds often reached several hundred meters on a side. It is likely

that these installations were connected by roads, some of which were later used by the Inca.

Huari culture arose from a blending of low sierra (Nasca) and high sierra (Pukara) traditions. Economically, Huari depended largely on dry farming of corn, with probable additions of other Andean staples, such as potato and quinoa. Huari domination of other areas was probably intended to extract agricultural surplus and control trade in rare materials, such as shell and salt. Specialization can be recognized at sites like Conchopata, which seems to have served as a ceramic production and ritual center. Well-defined and distinctive ceramic styles provide a tight chronology for Huari sites in its core territory near Ayacucho. Huari militarism, statecraft, and engineering are thought to represent antecedents of the later Inca Empire.

HUMAN CANOPY EVOLUTION

For more than 50 million years, the canopy environment has placed stringent evolutionary conditions upon existence within its domain. Primates are a result of that process. Some examples of primate adaptations traditionally attributed to evolution within the canopy include binocular and color vision, long arms and legs, fingernails, grasping thumb, broad shoulders, enlarged brain, vertical posture, giving birth to one young, and a head that sits at a right angle to the spine. Certain features once thought to have originated in the terrestrial environment have now been added to this, including bipedalism among large-bodied apes and a long, opposable thumb. Over the last decade and a half, fossil discoveries have

continued to strengthen the view of the canopy as a source of protohuman adaptations.

Since the time of Darwin, theories of human evolution have taught that the arrival of bipedalism brought an end to our dependence on trees. That event cut us loose from our boorish primate origins, freeing us to fulfill our destiny. Arrival at the ground was a fundamental turning point in our lineage that set our hands free to work miracles, and with that, we never once looked back at our arboreal birthplace. Yet since the discovery of *Australopithecus afarensis*, there has been a growing list of potential ancestors that have turned this view upside down. Not only were they active bipeds, they were also active climbers. These climbers are prominent names in our ancestry, such as *A. africanus*, *Homo habilis*, and *H. rudolfensis*, to name a few. Naturally, the ancestors of those early bipeds were also thought to have been climbers. As shown below, even *H. erectus*, who is viewed as exclusively terrestrial, used tools designed for canopy applications.

Oddly, the knowledge that our early bipedal ancestors spent considerable time in the canopy has not percolated down into theories about the evolution of human nature and the brain. The original theories, formulated from strained academic efforts to hide our affinities with apes over the past 150 years, promote an outdated terrestrial view of evolution that remains largely accepted and intact. “Canopy theory” unifies myriad disparate data into a single, cohesive, commonsense framework. Comparing terrestrial mammalian evolution during the Cenozoic with primate and marine mammal evolution raises doubts that the terrestrial environment could have been a habitat that promoted encephalization. Canopy theory encompasses early primate evolution and shows that the arboreal process of primate encephalization did not cease once our ancestors arrived at the ground. On the contrary, it shows that a reinvigorated arboreal encephalization process ultimately led to the human-sized brain. To demonstrate the strength of the canopy viewpoint within the space permitted, several of the more intractable problems that, as yet, lack satisfactory explanation will be discussed. These include the loss of thick body hair, tree platforms, and early weapons, such as the Acheulean hand axe.

Naked Ape in the Canopy

Primates are most noted in being quadrumanous, having four hands that are essential appendages for

safe travel in the canopy. Quadrumanous primate young cling to the mother's body until they are capable of independent travel. A few million years ago, evolution sidestepped when the hands at the end of our legs began to evolve into feet. From the canopy point of view, nothing could be more radical. Becoming bimanous greatly altered the behavior of our ancestors in their treetop habitat and led directly to changes in our morphology. This impacted reproductive behavior and drastically undercut the proven primate suite of coevolved adaptations between mother and young that determined how infants were transported from place to place.

Transforming a hand into a foot was a major engineering modification. Long fingers were converted into short stumps called toes, and what was an opposable thumb was realigned to become a nongripping big toe. This made the infants' toes useless for hanging onto the ancestral primate mother's gripping-fur. The infant had lost a pair of gripping hands, reducing its attachment points to the mother's body by 50%. This was a revolutionary mechanical shift in load that resulted in extremely high selective pressure. Gripping-fur and infant hands were a tight coevolutionary duo. Change in one immediately forced a complementary change in the other.

An example of coevolution can be seen between trumpet blossoms and hummingbirds. Some trumpet flowers gain reproductive advantage by limiting access to their nectar. This can occur simply by elongation of the floral tube. Over evolutionary time, hummingbird species responded with longer bills to match the changing depth of floral tubes. Close coevolutionary relationships like this have enriched the diversity of the planet's life by promoting new species.

The ancestral bimanous infant had a less secure grip on its mother's body. The traditional view explains that the bipedal mother accommodated this change by simply retaining her gripping-fur and holding the baby with her arms, while her hips broadened into a sort of saddle on which to carry her young. But the fossil record tells us that broad hips did not arrive until the infant developed a larger cranial size, a more recent adaptation. Therefore, large hips could not have played a role in the adaptations needed to support the bimanous ape infant. In addition, the fossil record indicates that we still climbed trees when we were bimanous bipeds, and it can be reasonably inferred that hand carrying an infant while climbing would not have been possible. More

than ever, we needed our two remaining hands to climb; there were no spare hands to help an infant.

So, how were the young carried? Did they hang with full body weight from two fistfuls of gripping-fur as the mother clambered amongst limbs? From a purely mechanical point of view, climbing is a tortuous activity that can require swings, rapid turns, accelerations, decelerations, and other acrobatic feats. For an infant trying to cling to its mother, the loss of two attachment points would have resulted in a major and deadly mechanical instability. At times, a bimanous infant would pendulum, shifting full body weight from hand to hand. This would produce forces well over a 100% greater than those endured by the infant quadrumanous ancestor. Either the gripping-fur would have pulled out or the infant would have lost its grip. Hanging from two hands or being supported in the mother's arms would have led to extinction.

One coevolutionary solution to the reduction in attachment points would have been to increase the holding power of the infant's remaining two hands. Babies today do seem to have an unusually strong grip reflex. The increased strength of the infant handhold would have been matched by an increase in the strength and length of gripping-fur on the mother's body. This would help ease the tension that developed between the coevolved hand/gripping-fur pair. And this is exactly what happened. Of all apes, we have the thickest, strongest, and longest hair, but that gripping-fur does not cover our bodies. It is found only on the head.

So, why do we have long, strong gripping-hair only on our heads? Because the bimanous grip on body hair was still risky. Safety (natural selection) required that long, strong, gripping-hair be located adjacent to a stout support position for the lower part of the infant's body that no longer had gripping hands. There is but one location on the human body where that evolutionary formula fits: the shoulders. If this sounds awkward, remember that infant size was smaller, and the infant might have been more precocious than today. Perhaps this is why children love to be carried in that fashion. Humans have longer necks than apes, suggesting the ancestral neck may have lengthened around the time feet lost their ability to grip.

With hands clutching the mother's gripping-hair and legs securely around the neck, the infant's weight rested in the only mechanically safe position available. Long head hair, a long neck, and lack of gripping-fur

on the body are the results of a coevolutionary process associated with successful reproduction. We are the only “naked ape” specifically because we are the sole extant bimanous ape. Other explanations that have been advanced for the loss of hair, such as thermoregulation, parasites, swimming, and sexual selection, may have acted to reinforce the coevolutionary changes between mother and infant, but not necessarily.

Grip-Climbing in the Canopy

The structure and function of the feet of all mammals require or allow certain forms of behavior and preclude others. The bimanous ancestor that led to humanity would have climbed differently from a quadrumanous ape and would have used the spaces within a tree differently. The shorter fingers, expanded apical tufts, and longer thumb of the bimanous biped are adaptations for grip-climbing; not for toolmaking, as has always been claimed, and not for suspensory climbing. Grip-climbing requires holding onto large-diameter limbs and trunks that have bark grooves; it employs the thumb to a greater degree. The bimanous ancestor was specialized for climbing within tree crowns among the larger branches where weight is borne on the foot while standing in a vertical position.

Conversely, the quadrumanous ape's long fingers and a shorter thumb are well designed for suspension from branches, providing much safer access to the distal portion of limbs. Sometimes, fossils that have humanlike features are compared to chimpanzee skeletons to try to decide whether or not the fossil ancestor was arboreal. But since the bimanous hand evolved for grip-climbing and for access to the internal tree crown, rather than for suspensory climbing, one cannot directly compare a bimanous skeleton to a chimpanzee and come away with a reliable estimate of the time a bimanous ape spent in trees.

Neocanopy

All great apes build nests, including humans, so there is little doubt that our bipedal ancestors would have built nests much like those made by apes. Recent views on the origin of human nature accept that our bipedal ancestors would have spent time sleeping in the canopy, and there is some acceptance that sleeping-tree locations may have contributed to various aspects of the fossil record. However, these meager

acknowledgments fall short of explaining what must have been taking place in the canopy.

H. sapiens, the only living bimanous apes, build tree platforms of a much different style than apes. This style is another facet of the transformation that occurred when our four-handed, bipedal ancestor lost the ability to grip with its feet and became a bimanous biped with an enlarged brain. This places the origin of improved “tree nests” during the time of *H. habilis*.

Becoming bimanous reduced safety, which would have been compensated for by building a stronger nest in a safer location. Safety translated into larger diameter limbs and stronger “nest” materials. Bimanous ancestors would have used trees with a shape and form that supported larger and stronger tree platforms. Ideal tree limbs were situated over water, where a soft landing was possible after a fall. Optimal tree locations inhibited predation by large cats and allowed simple aerial hunting. Stronger nests took more time to make, leading to reuse of nests. At some point, the bimanous tree nest became a tree platform.

Tree platforms were designed for the terrestrial foot. In subtle ways, the redesign of the quadrumanous nest into one that was bimanous created a totally new environment. That environment would have been unlike any canopy refuge of the past as it evolved into a kind of aerial home base. Canopy theory calls this neocanopy habitat the *terrarboreal habitat*.

Theorists have long sought an evolutionary feedback process that would promote ongoing brain evolution. The origin of the terrarboreal habitat offers a new explanation for the expansion of the brain of *Homo habilis*, about which little is understood. Canopy theory proposes that the terrarboreal habitat, along with associated inventions that improved safety and access to the canopy, was the principal force behind the evolution of the human mind. Specific activities that took place in the terrarboreal habitat led to humanlike social interactions, the earliest use of language in the command form, the development of weapons for defense and hunting, early aerial hut designs, and inventions such as roofs, knots, rope, and many others.

The archeological record is practically devoid of terrestrial home base and sleeping sites used by early and later bimana. Tree platforms would have provided dependable security from terrestrial predators,

whose strength and competitiveness have been routinely underestimated. Our ancestors spent most of their sleeping hours on canopy platforms. When boughs broke or trees fell, platforms crashed to the ground and were demolished, not likely to be exposed by the trowels of future scientists. Canopy theory speculates that our ancestors routinely used tree platforms until some time after around 50,000 years ago. Our move to a full-time terrestrial existence would have to remain tentative until we could protect ourselves against carnivorous competitors. Once that was achieved, we bade farewell to our birthplace in the trees and began a far different and in some ways more challenging and dangerous journey at the ground.

But such inferences bring us to a theoretical landscape, an uncharted “arboreal continent,” that has never been explored by human evolution theory. There are numerous partially written stories and vignettes locked in the attic of human origins waiting to be brought down and dusted off. One well-kept secret is that strength alone can turn a human into an active climber. *H. erectus* had basically the same body design as humans, but with a distinct arboreal advantage. Researchers describe the *H. erectus* arm and shoulder girdle as apelike and robust, meaning exceptionally strong. The upper arm and grip strength of *H. erectus* would have made the species better climbers than strong humans. *Robust* is a frequently used word in terrestrial theories. It is another secret that had been locked in the attic. Whenever a primate skeleton is robust and its body is human size and smaller, it is *always*, without exception, associated with arboreal activities. Although *H. erectus* is viewed as a terrestrial primate species, its body form tells us it climbed into the canopy. What was it doing there?

Hand Axe: A Canopy Tool

The hand axe is considered the calling card of the African *H. erectus*, but its exact use is still being debated. These axes are found from South Africa to Europe in the west and India in the east. Hand axes come in many different sizes, with a general trend toward reduction in size over time. The earliest Acheulean hand axes are dated at about 1.5 million years old and were found at Peninj, in West Natron, Tanzania, Africa. This section concentrates initially on early hand axes that have a general tear-drop shape, are about 10 inches long, and weigh about 5 pounds. Issues that remain unresolved are: Why

was such a large, hand-held tool bifacial? Why are they found in dense accumulations associated with ancient water? And why did the design remain basically unchanged for over a million years? All are answered by a single canopy explanation.

Hand axes resemble large spear points, but some weigh up to 50 pounds. This huge difference in size has given rise to several views on the tool’s use. There is no chance that the largest hand axes were thrown or used as spear points. Some researchers believe large hand axes represent early religious symbols, perhaps worshipped by a kind of Stone Age, hand axe cult. Even the 10-inch-long varieties could not have been hafted as a terrestrial spear, as the butt end would have been too thick. Some say these tools were large carving-and-skinning knives, and still others feel they were thrown at prey. However, neither underhand nor overhand throws would produce the velocity needed to make the hand axe a weapon.

A discuslike throw could produce the necessary velocity to debilitate prey, were it not for a glaring limitation of *H. erectus*. The vertebrae of the Turkana Boy, an *H. erectus* approximately 11 years old, show that the spinal cord opening of his species was considerably smaller than ours. Since the opening is for motor and sensory neurons, it has been concluded the species could not have had great coordination. It would have been impossible for *H. erectus* to perform the precise spinning motion needed to hurl a hand axe like a discus, even if such a throw could be aimed effectively. This limitation would apply to any hunting technique that requires highly coordinated activities.

Like empty gun-shell casings, hand axe sites are forensic evidence of their principal targets and form of use. Hand axes are typically found in unexpectedly high densities and in clumped distributions. Some locations have thousands of these artifacts piled on top of one another, while others have tens of thousands. If hand axes were used as hand-thrown terrestrial spears and throwing rocks, we would expect to see them more widely distributed, coinciding with animal distributions. But they aren’t. They are in large piles where they fell after they were used. The key to their use is the one-on-top-of-another accumulations.

Hand axes typically are found near ancient riparian habitats where large trees were likely to have grown. The hand axe was actually a “drop-chisel.” It was dropped from high arboreal positions onto prey.

Counterintuitively, the working end of the hand axe was not the pointed end; it was the chisel-shaped, blunt end. Kinetic energy of the falling hand axe was focused on a chisel edge, giving *H. erectus* a simple-yet-powerful hunting strategy that required little physical coordination. From lofty perches over ideal hunting grounds—watering holes, fishing pools, and river crossings—a vigilant eye kept watch over a diversity of creatures that congregated below. Hunting that took place in the same location, day after day, year after year, over hundreds if not thousands of years, would have been simpler from the comfort of a tree platform.

What about that meter-long, 22-kilogram hand axe? Was it really the first religious idol, or was it something far more practical? Carrying a heavy rock into the treetops could have been accomplished by a robust bimana, but holding the stone over a target while balancing on a limb would have been difficult. Use of this unwieldy tool would have required a tree platform. No longer can it be claimed bimana lacked an effective killing weapon.

Drop-Tools

The drop-chisel did not appear out of thin air; it had a predecessor. Drop-chisels evolved from “drop-rocks” associated with *H. habilis* and more ancient ancestors. These rocks would have been collected from riverbeds and talus slopes. Their use stemmed from the common primate habit of bombarding potential terrestrial threats with falling objects. Recognizing that drop-rocks would stun or kill small mammals and surface-feeding aquatic vertebrates, such as turtles and fish, would have been a natural outgrowth of typical primate behavior. Masses of irregular rocks, spheroid and choppers, have been found in the geologic strata known as Bed I at Olduvai Gorge. The present view of these accumulations is that they are stone caches; however, some appear to be deposited within light sediments and in aquatic settings. This indicates these “caches” were actually drop-rocks that settled to the bottom of a mud hole and/or accidentally fell off a tree platform and were lost.

Over time, an understanding of the merits of a tear-drop or fusiform rock over a round drop-rock would have dawned on our ancestors. A fusiform rock penetrates into water and therefore would have been a better fishing tool. As a hunting tool, a fusiform

rock cuts through skin, as opposed to a round rock that bounces off. This naturally occurring shape can be found in both talus slopes and fractured shale deposits, and superficial adjustments wouldn’t have required great intellectual prowess.

A natural, tear drop-shaped stone was used to test the manner in which the original drop-chisels were held. This stone was dropped from a height of 13 meters, a distance from which one can reliably strike a soup can. Practice is needed to guarantee a drop-chisel will strike edge first. How the drop-chisel is held is critical. Any rotation whatsoever imparted to the tool when it begins to fall tends to turn the leading edge parallel to the earth before it strikes the ground. Prey struck in that position might be stunned, but perhaps not killed. Think of a hand axe as a pendulum. It must be held by the pointed tip, and no matter how still it is held, it will swing a little at the chisel end. A thinner trailing end is easier to hold and more likely to fall true. A bifacial edge on the hand axe could have resulted from paring down the trailing end to provide a steadier grip. With sharp edges, even a near miss could result in a deep gash that would be at least debilitating. Continued tapering of the pointed end would produce a more stable drop-chisel shape known as an “Auchealean pick.”

Onetime use of some drop-chisels accounts for why they are often found in nearly perfect condition. It is unlikely that drop-chisels were ever discarded intentionally. They were retrieved from water and mud until lost, or at times, they may have been abandoned due to the ill intent of predators lurking below the surface.

Investigators report wood deposits on the Pininj drop-chisels, suggesting they may have been used to cut down straight saplings or branches for shafts. The drop-chisel’s sharp-pointed end was a self-hafting blade. Driving the blade into a shaft of green wood would split the wood, creating a pinching force that held the blade in place. The thick end remained the killing end. A wooden shaft combined with the stone would have weighed about 10 pounds. This increased weight improved killing power, and a long shaft fell straight and simplified hunting. The drop-spear was a huge step in drop-tool evolution, as it permitted the use of more recent, flatter hand axes and other shapes that were sharpened around the perimeter. Unwieldy as a terrestrial spear, the drop-spear was an ideal canopy weapon. Thrown at an angle rather than a

straight-down trajectory, the drop-spear became the first step in developing a terrestrial spear with a stone point.

Canopy Hunting Platforms

Hunting platforms probably originated during the early Stone Age. A huge effort has gone into trying to divine an answer as to whether or not our bimanous ancestors were hunters or scavengers. It is presently believed these early ancestors were scavengers based on the frequency of tooth marks found on fossil bones. But this determination has not taken canopy-hunting activities into account.

Early bimana would have discovered that leftovers tossed from tree platforms attracted animals. We also know that bimana accumulated stones from the countryside for use as tools. This brought them in contact with kill sites, where they collected long bones previously gnawed by carnivores and scavengers. Back on the tree platform, the bones were crushed, and the marrow was eaten. The remains were then dropped off the platform where they lay strewn below on a stream bank or possibly in the water. There, the leftovers would act as bait, attracting both terrestrial and aquatic vertebrates. After killing one of these scavengers, large chunks of meat were slashed off. Most writing about the subject assumes without question that during such butchery, the stone knives would have scratched the bone. This would not be true if the amount of food made available was in excess of the needs of the hunter. In that case, butchery would have taken place without scratching the bone, while leaving behind plenty of meat for scavengers to consume. Canopy hunting would likely guarantee kills in excess of needs. Below a hunting platform, one would expect to find bones that had been gnawed upon by predators, with few cut marks, as well as cracked and splintered shards of crushed long bones. Obviously, cut marks and tooth scrapes on bones do not tell us much about the activities of our ancestors, whereas bone assemblages, stone piles, drop-chisel design and accumulations, and the robust morphology of our ancestors point to a single conclusion: Our bimanous ancestors were effective canopy hunters.

Turning to some of the sites at Olduvai Gorge, site FXJj50 at Koobi Fora has characteristics that indicate it was a refuse pile from an ancient hunting platform where bait may have been used to attract prey. Bones may have been brought to the site that were already

gnawed by carnivores. One of the more interesting bone accumulations studied by Mary Leakey was the FLK- Zinj excavation in Olduvai Gorge. The bones in a portion of those accumulations had an arc-shaped assemblage, once interpreted as a windbreak. The “canopy view” is that the arc-shaped area may have resulted from the fallout shadow of an arboreal home base. Long bones of ungulates are the most frequently found bones in the pile, and it is thought that these were brought to the location from elsewhere. These could have been killed at platforms near watering holes, then brought back to the living platform in the canopy. At another Olduvai site, the percentage of carnivore remains in the bone assemblage reached 21%. This is an extremely high figure that is very unusual. This indicates carnivores were being attracted to bait under a tree platform, then killed as prey.

King of the Jungle

The present terrestrial view of our ancestors is that they were poor at protecting themselves, which was probably true out on the savanna. But an arboreal, bimanous biped who was capable of transporting heavy rocks would have been a formidable forest species. From a lookout in the canopy, movements of dangerous animals below could be observed vigilantly. Predators within the forest were driven off and/or injured. Our ancestors, not large cats, dominated select regions of closed and riparian forests.

The evolution of drop-chisels and drop-spears strengthened our ancestor's control over forested areas. This long-term control is demonstrated by fossil discoveries at Olorgesailie, Kenya. Artifacts there span hundreds of thousands of years and led to the discovery that hand axes did not change in shape over an extended period of time. One of the more intriguing bone accumulations at Olorgesailie included more than 60 giant-baboon skeletons intermingled with lost drop-chisels. A variety of scenarios have been suggested, but the logical explanation is that these formidable animals were slaughtered through stealth from above. Drop-spears were probably the weapons of choice. Olorgesailie is a classic canopy-hunting site. Data on changing biota and climate establish that over a long period of time, canopy hunting was a reliable way to obtain food. The long life of the drop-chisel establishes that its design was an invention like the wheel. When a tool fits its function, the function defines its form.

Neocanopy Brain Evolution

From the end of the Cretaceous period, the canopy environment stood apart from the ground as a habitat that could promote brain evolution. Primates evolved within that aerial habitat, where they developed a brain-to-body-weight ratio greater than all terrestrial mammals. This ratio changed little over tens of millions of years. During the proliferation of Miocene apes around 15 to 20 million years ago, many species of apes developed larger brains as a result of attaining a larger body size, but they still possessed a brain-to-body ratio little different from that of monkeys. At that point, brain expansion reached a plateau where chimpanzee brain size remains today, but in our lineage, a new spurt began about 3 million years ago. Encephalization in the canopy recommenced as our ancestors were becoming bimanous. The terrestrial habitat played only an indirect role limited to the transformation of a pair of grasping feet into nongrasping feet.

The physical adaptation process produced grip-climbing and modified the hand into its humanlike form. This precipitated simultaneous mental and behavioral adaptations. All of these were associated with the origin of terrarboreal platforms. Two or more individuals were needed to build the larger terrarboreal platforms. The terrarboreal habitat included platforms, roofs, walls, and probably, as with bonobos, more than a single family might have built within a single tree. When one individual was on the ground and another on the platform, the distance between them encouraged verbal and visual communication that led to rudimentary sign language and the first commands of a spoken language. Practical inventions of the terrarboreal habitat could have included rope, twine, knots, bags, and several types of drop-weapons. This author is confident that terrarboreal habitats and inventions needed to keep bimanous apes safe while living in the canopy will prove to be the single most important suite of mental changes and adaptations that acted together synergistically for the evolution of the human mind.

Traditionally, encephalization is attributed to activities taking place on the ground as a result of bipedalism. However, there are no biological examples that demonstrate that the terrestrial habitat can produce primateline encephalization. On the contrary, when primateline encephalization has occurred, it was a result of a “multiple-habitat effect,” a process described

by canopy theory. The parochial, paleoanthropological view that a terrestrial habitat promoted human brain encephalization lacks rudimentary biological support. No biological doubt exists about the canopy’s ability to promote encephalization. Given the existence of the terrarboreal habitat, we have arrived at the most compelling biological explanation to date for the growth of the brain: that growth was a neocanopy phenomenon that took place above ground in the evolving terrarboreal habitat.

Our ancestors did not walk along a dusty path on their journey to become human; they traveled arboreal highways of a lost, treetop world. Signposts from our passage through a canopy world can still be seen in ancient Greek columns, cathedral design, skyscrapers, hunting platforms, tree houses, children’s playgrounds, and the innate reflexes of infants. These represent vestigial sentiments and behaviors that sustained us during millions of years of intimate treetop evolution. The interwoven boughs of majestic forest trees, like mother and infant to be, were the nurturing womb of the human mind.

HUMAN COMPETITION AND STRESS

One common characteristic seen across the whole primate species is its competitive nature. Whether it's competing to rise in the status hierarchy or competing in the Super Bowl or Stanley Cup Finals, primates as a whole engage in competition regularly. During the competitive stages, several physiological and psychological changes take place. The physiological changes have been examined by way of measuring blood pressure, heartbeat, respiration, and perspiration. Though these measures help in the understanding of the physiological responses of stress, researchers are now able to further understand the nature of stress from a hormonal standpoint. One popular method of measuring one's physiological response to acute and chronic stress is by measuring salivary cortisol. This noninvasive method of analysis is especially useful in the athletic environment. Athletic competition is the preferred environment in which to study hormones and competition due to its highly organized and structured setting. This environment provides for clear rules and regulations and can also measure performance by way of wins/losses or other measures of individual performance. Understanding the underlying physiological and psychological responses to stress can have a significant effect on the way we view diseases such as heart disease, depression, anxiety, and even cancer. It has been well documented that chronic stress can have a debilitating effect on the immune system's ability to fight off infection and disease. Therefore, with the increasing demands of life, it comes as no surprise that stress is now having a significant impact on the quality of life that one lives.

Hormonal Responses to Stress

Stress can be defined as a physical and/or psychological response to life experiences that may challenge or threaten us. Furthermore, stress can be experienced both subjectively through anxiety, fear, anger, and depression as well as physiologically. Stress can be brought on by several negative life events, such as a death in the family, divorce, or relocation, or even positive events such as a big job promotion or winning the lottery. When faced with a stressful situation, the body activates the sympathetic nervous system, which through the hypothalamus-pituitary-adrenal (HPA) axis mediates a wide range of adaptive functions. The

stress response first begins in a deep structure within the brain known as the hypothalamus. The hypothalamus releases a protein known as the corticotropin-releasing factor (CRF), which then stimulates the pituitary gland. The pituitary gland then releases adrenocorticotropin hormone (ACTH), which, in turn, stimulates the release of cortisol from the adrenal gland. One way to measure HPA axis activation is by assessing cortisol levels. Cortisol has been found to be the most accepted marker of HPA axis activation. Furthermore, increased cortisol has been known to be an adaptive mechanism of the organism when stressed. Moderate increases in cortisol are known to prepare individuals for immediate or forthcoming action. This moderate increase enables one's blood to move from the extremities to the large muscles that are used in physical activity, and it has also been shown to play a positive role in cognition and emotions. In contrast, larger increases in cortisol have been shown to decrease performance by interfering with cognitive processes and also by lowering testosterone levels. Furthermore, chronic stress has been shown to have a significant negative effect on one's immune system.

Mazur's Biosocial Model of Status

Allan Mazur's biosocial model of status attempts to describe the hormonal changes that occur within one's body during face-to-face interaction. According to Mazur, status ranks are allocated among individuals or members of a group through face-to-face interactions, and this process is seen across the primate species. Mazur's model is based on the concept that primates, including humans, compete for status on a regular basis. During these "status" competitions, individuals attempt to "outstress" their competitor(s) through actions, nonverbal signs, or through verbal communication in humans. The winner(s) of the status contest assumes the higher or dominant rank, while the loser(s) assumes the lower rank. Studies have demonstrated that successful attempts to achieve or maintain status have led to increased levels of plasma or salivary testosterone levels. These studies suggest that rising or elevated testosterone levels are associated with assertive behavior, erect posture, strutting, and a general competitive nature. In contrast, diminished or depressed testosterone has been associated with submissive behavior, such as slumped posture and general acceptance of one's lower rank. In addition to

testosterone's role in preparing one for competition, Mazur's model also considers the relationship between competition and the stress experienced by individuals in response to or in anticipation of competition. Mazur's research shows that in most primate species, the lower-ranked members can be described as "nervous" or "insecure" during their interactions. These primates would be expected to display a greater degree of anxiety symptoms. On the contrary, higher-ranked primates appear to have a "relaxed" and "confident" demeanor, enabling them to cope more effectively with stressful situations. Therefore, Mazur's model suggests that winners would display the highest levels of testosterone and lowest levels of cortisol, while losers would tend to display lower levels of testosterone and higher levels of cortisol. This model lends support to the concept of a "winning streak" or a "losing streak." Winners of competitions seem to gather a sort of momentum after consecutive successful competitions, and this concept is very important in athletic competition as well as in the competitive business world.

Athletic Competition and Stress

As can be imagined, there are various forms of competition that can be observed, with a wide variation amongst the primate species. One form of competition that has been found to provide valuable feedback on hormonal activity during competition is athletic competition. This form of competition is a great environment in which to measure cortisol activity because there is a clear set of rules and regulations and also there is normally an unambiguous outcome leading to a winner and loser. Therefore, scientists seek to gain insight into the workings of hormones prior to, during, and after athletic competition. One of the questions that researchers seek to answer is whether there is an anticipatory stress response to the upcoming athletic competition. Most of the research on this topic has found that there is indeed an anticipatory rise in salivary cortisol and testosterone prior to competition. Suay et al. studied judo fighters in an attempt to demonstrate the anticipatory rise in hormones. Comparing precompetition saliva samples to samples obtained on 8 resting days, Suay et al. did indeed find an anticipatory rise in both cortisol and testosterone. Furthermore, in a study investigating hormonal responses to competition among a group of university tennis players,

Booth et al. found a rise in testosterone and cortisol just prior to the competitive event. These studies suggest that anticipatory rises in cortisol and testosterone serve to ready the individual for the forthcoming competition.

Another area of interest is whether winning or losing has an effect on salivary cortisol and testosterone levels. In a study on human competition, Gladue et al. did report a significant increase in testosterone levels of winners as compared to losers. However, their results did not produce any significant differences in cortisol levels between winners and losers. In contrast to Mazur's prediction of stress as proposed in his biosocial model of status, and perhaps counterintuitive, were the results from the studies of Elias and Suay et al. These studies both found significantly higher levels of salivary cortisol among the winners. This finding demonstrated that winners experienced significantly higher levels of stress than did the losers in the postcompetition phase.

Finally, important to the understanding of human competition is whether physical activity is the underlying cause of hormonal variation. Thus, can variations in salivary cortisol and testosterone be attributed to physical activity alone? Or is there a set of psychological variables that play an important role in the body's physiological response to competition? To study this question, researchers can study or evaluate their participants in noncompetitive settings that require intense physical activity and in settings that are considered competitive and also require intense physical activity. Suay et al. found similar rises in cortisol and testosterone in both competitive and noncompetitive physical activity settings. These results lend support to the idea that physical activity in both competitive and noncompetitive situations can significantly increase hormonal activity. Despite this evidence, other research has demonstrated that psychological variables have an important influence on the hormonal responses to competition. In a study investigating hormonal differences among NCAA hockey players, Putnam and Carré found no significant differences in salivary cortisol levels during a noncompetitive practice session. Although significant differences were not observed in this noncompetitive setting, the researchers did find statistically significant pre- to postgame rises in cortisol levels throughout the hockey season. This finding suggests that there is more than just physical activity that plays a role in the activation of the HPA axis, and there may

be numerous psychological variables that can affect one's physiological responses to athletic competition.

Stress and Disease

Although physiological responses to stress can be useful for short-term survival, excessive activation of the HPA axis can lead to disease and illness. For instance, high levels of cortisol can lead to a thinning of the lining of the stomach, which can lead to gastric ulcers. Furthermore, too much cortisol can also lead to thinning of one's bones, which can increase the likelihood of osteoporosis and also bone fractures. Studies with monkeys have found a strong correlation between stress and heart disease. These studies have shown that monkeys undergoing chronic social stress related to changes in their hierarchies found a strong relationship between stress and cardiovascular disease. Chronic stress can also have a profound effect on one's psychological well-being. It has been shown that excessive stress can lead to serious bouts of depression as well as anxiety disorders such as post-traumatic stress disorder. These disorders certainly have a psychological component; however, increases in HPA axis activation certainly contribute to the subjective experiences of the disorders. Furthermore, researchers have found that certain therapies geared toward reducing stress have had a positive impact on those treated. For instance, there have been numerous studies that have cited patients with compromised immune systems responding well to psychological intervention. These studies indicate that being able to cope with stress can have a profound effect on one's immune system and his or her ability to fight off infection.

Research on the physiological and psychological effects of stress have enabled researchers to have a better understanding of how the body responds to stress. Furthermore, research on athletic competition and hormone responses to stress has led to mixed results. These results suggest that there is a multitude of psychological factors that play a central role in the activation of the HPA axis. Therefore, more research into psychological factors, such as self-esteem, self-confidence, mood, and personality may provide additional clues to the overall process of stress and competition.

HUMAN DIGNITY

Human dignity is of central importance today, particularly in the fields of medical ethics and bioethics, as it represents a fundamental constituent of many contemporary constitutions, the most global being the Charter of the United Nations. It is, however, far from clear what the term *human dignity* means. The expression itself may be inappropriate, as it focuses solely on human beings. Perhaps we should use *the dignity of human beings* instead of *human dignity*, as the latter implies that human beings have dignity, whereas the dignity of human beings implies that dignity has a foundation and that it applies to human beings but can also apply to other creatures. The foundation of dignity, according to Kant, is the actual ability for autonomy. He stressed that human beings have that ability but that it is also possible for other creatures.

We distinguish between two types of dignity. One implies equality and one implies a certain hierarchy. The type of dignity relevant for our constitutions and ethical debates is that which implies equality among the bearers of that dignity. The first philosopher who

mentioned that type of dignity was Cicero in his *De Officiis*.

The other type of dignity, hierarchial, is older and is linked to abilities. If someone has X, then that person has dignity. The more X people have, the more dignity they have. X can be power, strength, beauty, reputation, or many other things.

Dignity that implies equality can have necessary or contingent foundations. If we decide that the basis of our governing constitution is dignity of this sort but we don't hold that this dignity is a natural constituent of human beings, then the dignity has a *contingent foundation*. If we hold dignity as being a natural constituent, then the dignity has a *necessary foundation*. The trouble with contingent foundations is that we cannot claim ethical superiority relative to other governments that do not place the dignity of human beings as the basis of their constitution, but hold, for example, the concept of human slavery as right and proper.

If we wish to claim ethical superiority, then we have to hold that dignity is a natural constituent of human beings or that it has a necessary foundation. The problem here is with the enormity of the claim that we have grasped the nature of human beings and that part of that nature is a dignity that all human beings share in the same manner. Most philosophers during the last century have abandoned making claims about the essence of the world.

What are the necessary foundations? In the history of ethics, the three most popular foundations are

- reason
- freedom
- likeness to God's image

We can find each of these in most foundations of dignity, although one aspect may be emphasized over the others.

If we believe that reason is the foundation, we must clarify what type of reason. Reason can be the means to live a good life (good for ourselves) or to live a moral life (impartially right). We can distinguish between the potential ability of reason, the actual ability of reason without necessarily acting on it, and actual ability of reason as the necessary basis of our actions. Kant suggested that the actual ability for autonomy is the foundation of human dignity, but he linked reason to each of the other foundations of dignity as well.

In the context of being a foundation of dignity, freedom usually refers to metaphysical autonomy and connects with an eternal soul without beginning or end or a soul that we create ourselves before time and space. On the basis of the preferences of our souls, we freely decide our acts. Pico della Mirandola regards freedom as the foundation of our dignity.

Our likeness to God's image is the third of the most popular foundations of dignity. Our similarity can be represented in reason, having an immaterial soul, or being free. It becomes clear, then, that freedom, God's image, soul, and reason are closely connected. If we hold that our dignity is based on our being created in God's image, as Thomas Aquinas or Manetti do, we can still wonder from which moment to which other moment do we have dignity. Of course, this is from the moment when body and soul are united to the moment when they are separated again, but when are these moments? Some believe that we are brought to life from the moment of the fusion of sperm and egg. Thomas Aquinas, on the other hand, held that it takes place 40 days after conception for boys and 80 to 90 days after conception for girls.

If we have dignity, what does this imply? Possible implications come in the form of rights and duties.

Rights can follow necessarily or contingently. There are positive rights (for example, to receive something) and negative rights (such as the right to take action). A positive right implies that others ought to support us concerning X. A negative right implies that we ought not to be obstructed in doing X. The positive right to live can mean that others have the duty to support you if you fail to survive by yourself or if someone tries to take your life. So we still must distinguish between the positive right to have something and the positive right to keep what we have.

Duties can also follow necessarily or contingently from dignity. As with rights, duties may be positive (such as the duty to take action) and negative (for example, to refrain from something). We must also differentiate between our duties and the duties of others.

We can further define rights and duties by dividing them into ethical, moral, or legal categories. Ethical rights or duties are always those that are good for ourselves. Moral ones are those rights or duties that are impartially right. Legal rights or duties correspond to the law.

In the history of philosophy, we have given Cicero, Manetti, Pico della Mirandola, and Kant the most

importance in their views of the foundations of dignity. In the contemporary debate, the positions of Margalit, Gewirth, and Habermas are particularly noteworthy. The most vehement, explicit, and pointed critique of dignity was made by Nietzsche.

HUMAN EXCELLENCE

As a term indicating well-developed skills pertaining to performing various tasks for personal gain and group benefit, *human excellence* may be found in all cultures. As a perfected ability in carrying out assigned work for survival, whether in hunting, war, or other activities, such as ritual dancing, excellence has been valued and recognized as well as rewarded, especially when exhibited in defending a group, tribal property, or, as often is the case, expanding territorial limits to obtain better living conditions. In general, the concept of excellence sets the boundaries for all efforts of continuous improvement.

The term has also been used to refer to bodily skills in competitive situations, such as games and exhibitions, taking on the meaning of “best” as in the case of individuals who have earned the reputation of being “the best” by having supremely trained skills worthy of imitation by and transmission to other members of the tribal group. Excellence thus takes its place among desirable social traits, urging the continuation of an established value. In Homer’s *Iliad*, a father advises his son who is leaving for battle, “Always excel and remain better than others.”

The list of bodily skills eventually was expanded in certain cultures to include personality traits covering activities related to powers of the “soul.” In the history

of the development of the concept of excellence, the Ancient Greeks made the first successful attempt to define the meaning of excellence within an enlarged scope of human activities to refer to all pursuits, beyond the needed training steps for the acquisition of military skills. They introduced theoretical considerations that facilitated the understanding of the conditions indispensable for securing the educational process, which leads from having an initial ability to perfecting it. Criteria for evaluating such attainable perfection became an object of inquiry, debate, and critical discussion.

Recommending and praising excellence was central to the life of Greece as well as a dominant feature in the arts, from poetry to architecture. As a concept, it permeated all walks of life and was adopted for all models of performance. To put it somewhat differently, excellence applied to both artist and artistic work. The Greek word *aretē*, usually translated as “virtue,” and the related cognates of *aristeia* and *agathon*, including their derivatives, were used in a great variety of contexts referring to private and public activities, from shipmaking and legislating to public speaking and athletics. Eventually, with the maturing of philosophy, excellence became an indispensable trait of all ways of rational thought. Thus, a person was expected to exhibit his or her best in action as well as in thought, expecting in turn to be evaluated on the basis of explicit criteria known in advance and established as tradition. Such, then, was the rise and consolidation of a practical and reflective framework that led to the formulation of a philosophical treatment of excellence. It came to refer to a highly valued type of conduct that is usually translated in contemporary parlance as “moral virtue.”

It should be noted that the concept itself, at least as it occurs in Greek culture, had a considerably wider meaning, exceeding that of commendable “moral” properties. In classical philosophy, excellence was treated in depth and used to cover ethical and political skills (i.e., “practical”) as well as skills appropriate to acquiring knowledge (i.e., “theoretical”). The Greeks also spoke of ethical persons possessing excellence of character in the same way they referred to “right” or well-governed *poleis*, what we now call “city-states.” In this refined sense of excellence, whereby “good” is taken to mean perfected and working traits, it came to apply to anything that possessed the characteristic features of a well-finished product or work as the outcome of *technē* (poetics). In this

Martial artists focus their mental and physical energies.

widened context, a city having the right laws constituted the proper environment to breed excellent citizens. Inquiry, on the other hand, into the conditions and the criteria of excellence as *aretē* and their justification became a fundamental concern not only of poets but more so of philosophers, as we witness when reading the works of Plato and Aristotle. What had started earlier, as found in the surviving fragments of the pre-Socratics, became the subject of extensive treatment of excellence, thus contributing largely to the understanding as well as the promotion of this comprehensive use of *aretē* as a political, ethical, artistic, scientific, or religious value expected to accompany all institutionalized forms of conducts. It was recognized as an ideal that defined the meaning of praiseworthy “cultural conduct.”

Seen as commendable ideals, the types of excellence the Greeks sought to clarify and establish as central to their culture became models of reference that were

passed on to other cultures. In fact, they found a place in the institutions and patterns of values in the cultures of a variety of people that came in contact with the Greeks. This is true of the Romans as well as others who responded to the need to articulate their own conceptions of excellence and place them within a theoretical framework. It was in this connection that the idea of excellence was accepted and reformulated in the ways demanded of religious conduct as, for instance, in the case of Christian ethics. Its spokesmen in the course of time came up with a set of virtues appropriate to and supportive of its religious way of life. Although they made the Greek conception of virtues peripheral to theirs, the Christian theologians adopted the Greek reflective approach to excellence mainly to deepen, defend, and explain their own salvation moral stance.

The diverse antagonisms between different sets of virtues in the history of cultural outlooks, whether of the Western or other type, are characteristic of cultural disagreements and their continuous confrontations, often leading to serious conflicts and destructive wars. Be that as it may, the copresence of conflict-

ing sets of virtues within the same culture, such as the Western type contains, renders inevitable all sorts of clashes between differing groups even within a given institution (for example, religion or art, even scientific organizations and philosophical schools). Many reform movements in political life that have sought to reconcile conflicting values actually concern incompatible conceptions of excellence, nurtured and sustained within the same culture. While they last, such differences affect in varying degrees and with anomalous results the institutions and their modes of interaction.

Revisions of conceptions of excellence have been a much-heralded concern of leaders in politics, religious life, as well as education. The purpose in so doing has often been more than seeking to supply justification for the priority and supremacy of a favored position regarding excellence. What seems to affect the foreground of conflicting values and their continuous presence in various cultures is mainly the

unacknowledged force of different conceptions of human nature operating in the background. Usually such different views, fundamental as they are to the selection and promotion of a pattern of excellence, are rarely sorted out and systematically subjected to the tests of scientific investigation. Even science itself, with all its merits of being open to public inspection and its reliability as a shared method of inquiry, is not readily acceptable as the reasonable arbiter to weigh the impact of conflicting elements and effect their removal from the body of cultural beliefs. This is especially applicable to the case of differing conceptions of human nature. Finding common grounds for accepting rationally formulated criteria regarding the soundness of operating views of human nature has proved to be a most disagreeable enterprise.

To conclude, the concept of excellence, as it developed from an element of conviction regarding the valued skills that ensure survival, to perfected abilities and praiseworthy behavior in public and private conduct, manifests itself as a basic cultural component in every cultural institution. It is interesting to note that the Greek philosophers were the first to offer a solution to the vexing problem of establishing coherence in a set of excellences fundamental to their culture. The coherent pattern is known as the “doctrine of the unity of virtues.” The quest for excellence has never ceased to function as the source of an attitude that supports cherished aspirations, just as it continues to instigate violent disagreements in environments where different cultural perspectives enter in a confluent course, often generating unresolved conflicts and destructive actions. As a concept, it remains indispensable to guiding human conduct, but as an objective pursued in different and conflicting outlooks within the same culture, it often generates discordant forces, giving rise to serious political and educational discrepancies that make cultural cohesion almost impossible.

HUMAN GENOME PROJECT

The Human Genome Project (HGP) is an international project that was coordinated by the U.S. Department of Energy and the National Institutes of Health. Other major partners and additional contributions came from the United Kingdom, France, Germany, Japan, and China. This project was formally initiated in October 1990 and finally completed in 2003. However, analyses of these data will continue for many years to follow.

The goals of HGP were to identify all the genes in human DNA (which is approximately 20,000 to 25,000), determine all of the sequences of the chemical base pairs (about 3 billion) that make up human DNA, store this information and make it available in databases, make improvements on tools used for data analysis, eventually transfer related technologies to the private biotechnology sectors, and address the legal, social, and ethical issues that will ultimately arise as a result of the completion of this project.

Many benefits have been projected as a result of HGP. The benefits from genomic research have potential applications in areas of molecular medicine, energy sources and environmental applications, risk assessment, bioarchaeology, anthropology, evolution, human migration, DNA forensics (identification), agriculture, livestock breeding, and bioprocessing. In addition, commercial development of genomics research will provide U.S. industry with several lucrative opportunities from the sales of DNA-based products and technologies. Overall profits in biotechnology industry are projected to exceed \$45 billion by 2009.

In regard to molecular medicine (a branch of medicine that deals with the influence of gene expression on disease processes and with genetically based treatments, such as gene therapy), HGP has provided

technology and resources that have already had a widespread impact on biomedical research and clinical medicine. This is being made possible by increasingly detailed genome maps, which have assisted medical researchers in identifying genes associated with several genetic conditions. Clinical improvements will also be seen with more accurate diagnosis of disease, earlier detection of genetic predispositions to disease, rational drug design, gene therapy and control systems for drugs, and pharmacogenomics (the application of a genomic approach to the identification of biological drug targets and interactions). In short, molecular medicine will be defined less by treating symptoms of a disease and more by addressing the fundamental (or genetic) causes of a disease and its pathology.

HGP will also have applications in energy and the environment. Technology initiated in HGP can be utilized in the Microbial Genome Program, which is aimed to sequence the genomes of bacteria useful in energy production, environmental remediation, toxic waste reduction, and industrial processing. Microbial genomics research can be used to create new energy sources (called “biofuels”), to develop environmental monitoring techniques to detect pollutants, to develop safe and efficient environmental remediation, and to develop research for carbon sequestration. In addition, microbial genomics will help researchers to better understand how pathogenic microbes cause disease. Furthermore, research on microbial communities can provide models for understanding biological interactions and evolutionary history.

Understanding the human genome will have a significant impact on scientists’ ability to assess health risks posed to individuals exposed to toxic agents; this is known as “risk assessment.” This will be possible by examining the genome to identifying gene(s) that will increase the likelihood of potential harm. Therefore, HGP can improve the assessment of health damage and risks caused by radiation exposure, inducing low-dose exposures, exposure to mutagenic chemicals, cancer-causing toxins, and reducing the likelihood of heritable mutations.

Our understanding of human evolution and the common biology that humankind shares with all life will be improved by understanding genomics. Therefore, HGP will enhance our ability to more effectively study evolution through germ line mutation in lineages, study migration patterns of different types

of populations based on female genetic inheritance, study mutations on the Y chromosome to trace lineage and migration of males, and to compare breakpoints in the evolution of mutations with ages of populations and historical events. Comparative genomics between humans and mice have already showed similarities in genes associated with disease and traits, which is useful in developing research models. The function of thousands of other genes with unknown functions can be determined by additional comparative studies. In addition, the comparison of DNA sequences of the genomes of different microbes can provide new insight in regard to the kingdoms of life: eukaryotes, prokaryotes, and archaeobacteria (which is considered and presently classified an ancient life form that preceded and evolved separately from later bacteria and blue-green algae).

In DNA forensics, data from HGP will improve our ability to identify potential suspects whose DNA may match evidence left at a crime scene; exonerate individuals wrongly accused of a crime; identify crime and catastrophe victims; establish paternity and other family relationships; identify endangered and protected species (could be used to prosecute poachers); detect bacteria and other organisms that may pollute air, water, food, and soil; match organ donors with recipients; and determine pedigree for seed or livestock breeds. This will be made possible because any type of organism can be identified by the examination of a DNA sequence, which is unique to that species. To identify individuals, forensic scientists will scan about 10 DNA regions that vary from person to person and use this information to create a DNA profile of that individual (called a “DNA fingerprint”).

In agriculture, the understanding of plant and animal genomes will allow the development of genetic modifications to yield crops that are disease-, insect-, and drought-resistant as well as healthier, more productive, and disease-resistant livestock. An example of the benefits gained would be that disease-resistant crops would require little or no pesticides. This would be beneficial because pesticides can be hazardous to humans, and pesticides are expensive, which adds to the cost of production. Therefore, safer and less expensive food can be grown. In addition, larger and more nutritious fruits and vegetables can be grown. It is also conceivable that edible vaccinations can be incorporated into new food products.

A very complicated science is behind the completion of HGP. In a basic sense, DNA from every organism possesses the same chemical components (i.e., a 5-carbon sugar group, a phosphate group, and a nitrogenous base). An organism's complete set of DNA is known as a *genome*. DNA is typically arranged into a distinct unit called a "chromosome." Each chromosome contains specific regions called *genes*, which are the basic physical functional units of heredity. Genes contain instructions that encode how to make proteins, which ultimately perform most biological functions. The total arrangement of a cell's protein is referred to as its *proteome*.

Each protein has a specific chemical composition and biological function, which are provided by instructions from a particular gene. Many genetic diseases are attributed to an irregularity in the structure and/or function of a protein, which is directly connected to an error in the base pairs of that specific gene. Consequently, a gene with a mistake in its base pairing will yield an abnormal protein, which is manifested by an abnormal physiology. Examples of this would include an abnormal structure in one of the proteins of a red blood cell, resulting in its inability to properly carry oxygen molecules (seen in anemia) or an abnormal protein structure of a sodium channel, which results in the inability of a cell to function properly, causing gastrointestinal and respiratory problems (seen in cystic fibrosis). Research that is geared toward protein structure and function is now becoming the main focus in order to provide insight into the molecular basis of medical health. This area of study is known as *proteomics*.

How is sequencing of the genome done? In the initial "subcloning step," the chromosomes are chemically broken down into smaller pieces, which are easier to work with. Next, each piece is used as a template (the *template preparation step*), which is, in turn, used to generate sets of fragments (the *sequencing reaction step*) that differ in length by one base pair. The newly sequenced fragments are then separated by a biochemical technique known as *gel electrophoresis*; this process is the *separation step*. The final step (the *base-calling step*) recreates the original sequence of each short piece generated in the subcloning step; this is analyzed by automated sequencers and read by computers (known as *bio-informatics*), which assemble the small sequences into a long, continuous strand that is examined for errors. The completed sequence is sent to a major

public sequence database and made available to everyone around the world.

In the future, technology and genetic bioengineering may merge together and combine with information from the HGP to make it possible to "enhance" the human genome of an individual, thus potentially enriching the gene pool. Of course, this is very controversial and arouses many ethical and religious concerns. This technology is seen in a new area of medicine called "gene therapy," which is the treatment of genetic disorders, anomalies, or deficiencies by introducing specific engineered genes into a patient's cells. Presently, this is being introduced as a treatment option for diseases like prostate cancer.

Up until now, a tremendous amount of benefits has been enumerated and discussed, and consequently a typhoon of excitement has been created about a new era to come. However, there are many ethical, legal, and social implications that will need to be addressed in the new "postgenomic" era.

Much concern has been raised as to the fairness in the use of personal genetic information. It will need to be determined who should have access to personal genetic information and how to use it ethically and legally. This will need to be established so that insurance agencies, employers, courts, and schools do not use this information unfairly or discriminate against individuals based on their genomes. In addition, it will be important to decide who will legally own and control this information and what type of privacy and confidentiality will be ensured.

There are also concerns regarding genetically modified foods, as to whether they are safe for human consumption and to the environment or if they will have adverse effects on people's health. Research will have to be conducted to determine any detrimental effects or health risks associated with consuming genetically modified products.

Many clinical issues will also need to be resolved. For example, how are genetic tests evaluated or regulated for accuracy and reliability? Presently, there is little or no federal regulation in regard to genetic tests in the clinic. Other clinical issues will need to be addressed, such as whether we are prepared for the changes that will take place. It also needs to be assessed as to whether or not health care professionals are prepared to deal with the new genetics in a clinical setting. Ultimately, this may lead to changes in a clinician's education and certification standards. Also, it needs to be determined whether the public is being

prepared to make an educated and informed choice regarding genetic testing and the possible advent of gene therapy.

The new age of gene therapy also conjures up concerns in regard to what will be defined as required medical treatment and what is classified as genetic enhancement. Ethically, should people be allowed to enhance their genomes when it is not medically necessary? And what type of regulations will be set in place? In addition, it is conceivable that only the wealthy may be able to afford genetic enhancement. It may be also conceivable that this could give rise to a superior genetically enhanced upper class and a reciprocally inferior genetically unenhanced lower class. Or will it be possible for genetic enhancement to be equally available? This may create a “separation of class based on the availability of genetic enhancement.” It is also conceivable that this could provide the next step in human evolution, leading to a new form of our species.

Philosophical beliefs will also be challenged as a result of the completion of HGP in regard to ideas such as free will. For example, if an individual’s genome and genetic makeup are determined and mapped, will we arrive at the conclusion that an individual’s genetic makeup dictates individual behavior and choice? If a genome can be altered or genetically enhanced, then there is the possibility that an individual’s behavior may be controllable, negating the tender notion of free will and individuality.

In the future, due to the tremendous benefits that will be provided as a result of HGP, progress should be allowed to continue. However, guidelines need to be provided by educated, informed, and just individuals to ensure that new technology is not used to discriminate against individuals unjustly. Long-term goals should include the development of technology to protect all individuals’ “genetic privacy,” as well as addressing ethical and philosophical concerns. In short, the benefits should outweigh any short-term setbacks.

— John K. Grandy

HUMAN PALEONTOLOGY

Paleontology is the study of fossil animals and plants. Human paleontology focuses exclusively on fossils related to the human lineage. Human paleontology is highly interdisciplinary; to recover, describe, and interpret human fossil remains, its researchers need knowledge of cultural anthropology, archaeology, biology, paleontology, and geology.

Paleontology and Human Paleontology

Fossils, the remains or imprints of dead organisms, are the only physical evidence humans possess of ancient life. While fossils are generally formed from bone, shell, or wood, under very specific conditions, fossils may be formed from soft tissue, animal tracks, skin impressions, and feces. Sometimes, bones are disturbed by scavengers or water movement prior to fossilization; the study of what happens to a bone from the time of the organism’s death to its discovery is called *taphonomy*.

Research in paleontology focuses on reconstructing the history of life on Earth. Fossils provide important clues about past environments, ecosystems, and evolution. Paleontology incorporates knowledge from many fields to understand the processes of evolution and to reconstruct ancient life. Most fossils studied by paleontologists are anywhere from thousands to several millions of years old. Human paleontology focuses on fossils of the human lineage, thought to begin between 5 and 8 million years ago.

Like paleontology, human paleontology utilizes evolutionary theory and the scientific method to test hypotheses about past lifeways and relationships. Ecological niche theory and estimates of inter- and intraspecific competition levels also help reconstruct behaviors and evolutionary pressures. Morphometric and cladistic methodologies help researchers define

fossil species and reconstruct relationships between fossil species and between fossil and living species.

However, human paleontology differs from paleontology in that it studies human origins. This self-reflexive process, humans studying humans, is subject to bias not seen in studying, say, the evolution of birds. Most animals transmit information from generation to generation primarily through genetics (the purview of biological evolution). However, humans have a well-developed ability to pass information along through culture: teaching and learning. While culture is by no means exclusive to humans, humans utilize it so very heavily that it has arguably interfered with evolutionary pressures normally experienced by other animals.

Because of the heavy influence of culture on human adaptation, the application of some paleontological methods can be problematic. While early fossil humans, like other animals, had to adapt biologically and behaviorally to specific environments or ecological niches via natural selection, this is less true for later fossil humans. When fossil humans began to rely on cultural adaptations, such as fire and toolmaking, to assist them in survival, these adaptations created a cultural buffer between them and their environment. If humans can warm themselves through the controlled use of fire, winters are no longer as dangerous as they once were. Communication/language skills and technological sophistication have played large roles in shaping human adaptation to the environment. It is difficult to know how to interpret to what extent the forces of natural selection affected the survival of a species that relies so heavily on technology.

The terms human *paleontology* and *paleoanthropology* are often used interchangeably, although the former is primarily focused on the study of human fossils and the latter is a broader multidisciplinary activity. Paleontology does not usually deal with artifacts made by humans, but due to the uniqueness of the human biocultural adaptation, human paleontologists do look at artifacts as well as modern human and primate behavior to better understand the fossil record and humans' place in nature.

Areas of Research Within Human Paleontology

The human fossil record, like all fossil records, is incomplete. Fossil skeletons are rarely complete. Only a very small percentage of the original members of

any species experienced the accident of preservation as fossils. The challenge for human paleontologists is to reconstruct anatomy, behavior, and ecology from these specimens.

Osteology is the study of the structure and function of bones. The structure of bones is genetically based, but bones also respond to developmental events, stresses, and injuries to the body. Human paleontologists have to become very familiar with variation (between sexes, within any population, and between populations) exhibited by the modern human species. Some of this variation is genetic, but variation is also caused by unique life events experienced by the individual. The definition of fossil species rests on understanding of how much variation existed in the past, a difficult question, indeed. Familiarity with the principles of biomechanics (the study of the forces exerted by muscles and gravity on the skeleton) and the skeletons of primates and other animals help human paleontologists reconstruct the movement and behavior of fossil humans.

Dental anthropology, or the study of the dental evolution, variation, and morphology of modern and ancient human populations, is also a vital area of inquiry. Since teeth are composed of enamel, the hardest substance in the body, they are more likely to survive in the fossil record. Teeth are an important source of data in the reconstruction of fossil human diet, behavior, and species variation. Through the study of anatomy, human paleontologists can describe a species' size, diet, locomotor style, ecology, and even shed light on behavioral issues such as group size and social organization.

Human paleontologists use genetics to help answer questions about recent common ancestry and past population movements. They can measure how closely two species are related by comparing their DNA. Species that are similar genetically share an ancestor in the not-too-distant past. When geneticists compare human and chimpanzee DNA sequences, less than 2% of the sequences are different, meaning that these two species have a very recent common ancestor. Human paleontologists can estimate how long ago two species shared a common ancestor by using a "molecular clock," which calibrates an estimated mutation rate against time of divergence of different lineages. Scientists also use the concept of a molecular clock, but use mitochondrial DNA (or mtDNA) to track past population movements and to determine when and where the earliest modern human ancestor lived.

Finally, human paleontologists must look to behavioral models seen in modern humans and living primates to interpret fossil human behavior. Primate and human ecological models inform research on dietary adaptations and food-getting strategies, activity patterns, ranging behavior, and male/female reproductive strategies and social hierarchies.

A holistic anatomical study, including paleobotanic, paleontological, and paleoenvironmental associations, combined with molecular genetics and studies of behavioral models help human paleontologists understand the broader picture of human evolution.

HUMAN RIGHTS AND ANTHROPOLOGY

The term *human rights* refers to a set of legal and normative standards according to which all humans are ordained with certain rights irrespective of the cultural or social circumstances of their lives. Although the concept has considerable historical antecedents, modern human rights can be said to have been inaugurated with the establishment of the United Nations (UN) after World War II and that organization's adoption of the Universal Declaration of Human Rights. Since then, the number of organizations, treaties, and resolutions dedicated to human rights has multiplied dramatically.

The intersections between anthropology and human rights are numerous due to the increasingly vast range of issues covered under the rubric of human rights and the variety of topics addressed by anthropologists. The relationship between human rights and anthropology is made even more complex

by the coexistence of a strong undercurrent of a commitment to social justice and skepticism of human rights' emphasis on universalism in anthropology. Indeed, much of anthropology's early engagement with human rights specifically targeted the issue of relativism and the cultural specificity of ideas of human rights. Although most anthropological work prior to the 1990s did not explicitly examine human rights, anthropology has given rise to a rich body of work addressing pressing social problems, such as the impact of poverty and violence on the communities in which anthropologists do research. This body of work has given us a detailed record of the psychological effects of collective trauma, the use of cultural creativity as a coping mechanism, and the search for dignity in the midst of abject poverty. A recent offshoot of the anthropology of war and violence examines peace processes and attendant mechanisms such as postconflict tribunals and truth and reconciliation processes and their role in nation building. The idea of human rights is not merely a subject of study for anthropologists, however, but an increasingly significant influence on anthropological practice and how anthropologists interact with a range of interest groups. The emergence of claims to tangible and intangible cultural property rights and their subsidiary issues, such as that of the repatriation of material culture or skeletal remains to cultures or nations claiming those artifacts as part of their identity, has underlined the obligations of anthropologists to the communities in which they conduct research.

The History of Human Rights and Cultural Relativism

The foundational document of contemporary discussions of human rights is the Universal Declaration of Human Rights, a statement of aspirations and principles adopted by the UN General Assembly in 1948 as an expression of a commitment to a just world order, in which the horrors of World War II and the Holocaust would not be repeated. While the Universal Declaration drew upon a rich history of political thought and struggles against injustices, including the French and American Revolutions and the abolitionist struggle against the Atlantic slave trade, it signaled the hitherto most extensive commitment by many countries to a range of rights, including political, social, economic, and cultural ones. The Universal Declaration has been expanded upon,

further specified, and sometimes made legally binding through numerous subsequent conventions and resolutions. These include the International Covenant on Civil and Political Rights, the International Covenant on Economic, Social, and Cultural Rights, and conventions on the rights of women, slavery, and children's rights, among other issues. Important human rights work is also carried out by specialized UN agencies, such as the International Labor Organization (ILO), which has played a leading role in defining labor rights and the rights of indigenous peoples, and the United Nations Educational, Scientific, and Cultural Organization (UNESCO), which has played a leading role in defining rights to education and cultural rights. The three regional human rights systems in Africa (the African Commission on Human and People's Rights), Europe (the European Court of Human Rights), and the Americas (the Inter-American Court of Human Rights) add another layer of institutions dedicated to the protection and promotion of human rights. Finally, numerous nongovernmental organizations and research centers contribute to the global propagation and strengthening of human rights. International humanitarian law (the set of laws that governs the conduct of conflicts, including the Geneva conventions), while historically and conceptually distinct from human rights, increasingly overlaps with human rights law and is often included in discussions of human rights. Consequently, human rights do not constitute a coherent whole, but are an amalgamation of standards, norms, and principles that are not always wholly compatible and are not easily slotted into a hierarchy of importance. Indeed, many human rights controversies, including particularly contentious matters, such as female genital mutilation, are made more complex by conflicts between different rights, such as between the right to practice one's beliefs as one sees fit and the rights of women. In addition, human rights are often not justiciable; that is, there is often not a clear legal recourse available to groups or individuals who believe their rights have been violated. Where such a resource exists, it is often subjected to significant restrictions. Nonetheless, the importance of human rights as a global normative discourse is difficult to overstate, as it animates and legitimates a wide range of political and legal claims.

The American Anthropological Association was among the organizations consulted by UNESCO at the time of the drafting of the Universal Declaration

of Human Rights. The response was submitted to UNESCO in 1947, but there is no evidence that it was passed on to the drafters of the Universal Declaration. It was drafted by Melville J. Herskovits, a prominent anthropologist and a proponent of the idea of cultural relativism that had in some form dominated American anthropology since the work of Herskovits's teacher, Franz Boas. Cultural relativism was intended as a methodological or heuristic principle that held that a given practice can be understood only in the context of its culture. Informed by cultural relativism, the statement was a strongly worded argument for the tolerance of diversity and the biological unity of the human species, as well as a critique of racism and colonialism. It also suggested that values vary across cultures and any declaration of rights purporting to be universal must take that variation into account or simply be the expression of a particular culture's (or group of cultures') values. The worry, not unique to anthropologists, was that a list of rights and freedoms grounded in Western political thought and experience would be imposed on other cultures. Set against the background of European imperialism and the rhetoric of a civilizing mission justifying the colonization of most of Africa, South Asia, and other parts of the world, this admonition was wholly consistent with the anticolonial stance of the statement.

Cultural relativism has since then been largely misconstrued in many human rights debates into a version of moral relativism, suggesting that a cultural practice cannot be judged as right or wrong as long as it makes cultural sense. Cultural and moral relativism are not mutually exclusive, but the former does not necessarily lead to the latter. Despite occasional attempts by anthropologists to alter the terms of the debate, cultural relativism and universalism have remained the two poles around which much of the discussion has taken place. The proposition that human rights are a Western construct imposed in an imperialist fashion on peoples and cultures in the third world had considerable traction during the Cold War, during which the United States and its allies and the Soviet Union and its allies were proponents for different sets of rights (civil and political rights and socioeconomic rights, respectively). Proponents of "Asian values" similarly asserted that economic development should be prioritized over political freedoms and that many human rights, such as freedom of speech or assembly, reflect a Western individualistic culture and not the communitarian ethos attributed

to Asian cultures. Anthropologists have addressed these and other deployments of a crude cultural relativism for political purposes by noting the discrepancy between claims to cultural difference made by political leaders and the lived reality of their subjects, and by searching for cross-cultural equivalencies of human rights.

With the notable exception of the rights of indigenous peoples, anthropology was largely insignificant in substantive human rights debates beyond the issue of cultural relativism until the 1990s. Concern over discriminatory laws and policies, violence against indigenous peoples with the acquiescence of state authorities, the exploitation of indigenous people's territories by industrial operations, the harmful effects of environmental spoliation and degradation, and vulnerability to disease and substance abuse have prompted anthropologists to act as spokespersons for indigenous groups on every continent. Often working with indigenous scholars and activists, anthropologists have worked to rescue the history of indigenous peoples from the grand narrative of colonial expansion and to highlight the continued discrimination against and repression of indigenous peoples. Anthropologists have frequently argued against portrayals of indigenous groups as primitive remnants of an earlier age and advocated for the appropriateness and vitality of indigenous practices often overlooked by development and funding agencies in the management of natural resources. Anthropological research on the cultural traditions of indigenous groups has also been used by nationalist and indigenous movements to bolster claims to indigeneity. Anthropologists have, finally, also been actively involved in international efforts to promote and protect the status of indigenous peoples, such as the UN Permanent Forum on Indigenous Issues or nongovernmental organizations like Cultural Survival.

The research and advocacy on behalf of the status of indigenous peoples is but one instance in anthropology's disciplinary history of addressing social injustices and being a voice for marginalized groups. An early example of this commitment is Franz Boas's struggle against bigotry and racism in the United States. In the 1960s and 1970s, many anthropologists, often influenced by Marxism or some version of dependency or world systems theory, sought to document the impact of global capitalism on local communities and the third-world laborers whose work sustains the wealth of the West and local elites. This

work draws our attention to the fragmentation of social identities under global capitalism and the resultant vulnerability of communities, as well as the linkages between pauperization and economic exploitation on one hand and political and cultural marginalization on the other. Other work emphasizes the vitality of cultural traditions and the power of cultural practices and rituals to rearticulate impersonal corrosive global and regional forces into vernacular understandings of power and authority, hence making these forces approachable and ultimately contestable. More recently, other anthropologists have focused on the effect of structural violence on social problems, like famine or public health issues, such as the HIV/AIDS epidemic, arguing that these are often the result of, or exacerbated by, political decisions or willful ignorance. This work is, in turn, part of a long-standing interest in the social consequences of biomedical policies, particularly where they have consequences for human rights as in cases of forced sterilization.

Thus, since Boas, many anthropologists working under banners such as "action anthropology," "engaged anthropology," "public anthropology," and "public interest anthropology" have sought to address social injustices and promote social change. This scholarship, while for the most part not referencing human rights explicitly, nonetheless mirrors many of the concerns with the global human rights movement. Nonetheless, these partial exceptions aside, the scarcity of anthropological engagement with the growing international human rights regime is notable. Indeed, several anthropologists in the 1980s and early 1990s disapprovingly noted the paucity of anthropological studies of human rights and the institutions and individuals participating in their expansion.

The End of the Cold War and the Anthropology of Human Rights

The end of the Cold War in the early 1990s saw a resurgence of human rights and much talk of the victory of a Western liberal conception of human rights and the free market. The seemingly universal acceptance of human rights did little to stem the continued violent excesses and "dirty wars" of authoritarian governments, stop the outbreak of war and genocide (most notably the nearly simultaneous genocides in the former Yugoslavia and Rwanda and the Somalia crisis), or alleviate the crushing poverty of many third-world

countries exacerbated by an accelerating HIV/AIDS crisis. Within academia, cultural relativism lost some of its saliency, and the skepticism with which many scholars from across the social sciences and humanities had approached human rights receded by the first half of the 1990s. Anthropology itself underwent a dramatic period of self-scrutiny in the 1980s and paid a considerable amount of attention to the epistemological claims of anthropology, how these claims are constructed, and the relations of power and influence that enable those constructions in the first place.

A consequence of this period of theoretical upheaval was the transformation of the culture concept. The idea of a world of discreet cultures with their own conceptions of rights became increasingly untenable given the view of culture as a practice and something contested and negotiated. With the focus on power relations and the social maintenance of cultural boundaries, itself a mainstay of anthropology since the early work on ethnicity in the 1960s, statements of what a culture really is are increasingly difficult to make. Processes of globalization have further destabilized notions of culture to a point where the movement of goods, images, and ideas, including human rights, between culturally diverse contexts is part of the anthropological study, rather than a distraction. This confluence of factors has helped to propel human rights to the forefront of the anthropological imagination. As an institutional expression of this shift, the American Anthropological Association issued a new Declaration on Anthropology and Human Rights in 1999, which explicitly referenced the Universal Declaration of Human Rights and associated legal instruments as the baseline for anthropology's social commitment.

The reorientation of the relationship between anthropology and human rights away from previous discussions of relativity and cultural specificity to one where human rights themselves are considered cultural practices with particular social trajectories is an additional outcome of these shifting emphases within anthropology. From this vantage point, the question of whether particular human rights originate in a particular culture or have their equivalency in some other culture becomes less urgent. Instead, it becomes more important for anthropologists to study and describe how human rights are produced, by whom, in what contexts, and for what purposes. These human rights are disseminated through channels of communication and interaction that are empirically

traceable by anthropologists, and received and elaborated on by actors for specific strategic interests. Working in this mold, anthropologists have produced studies of the "arrival" of human rights in different countries that detail how local grievances are translated into human rights concerns and thus tap into a globally legitimate political idiom and transnational networks of organizations, knowledge, and resources. A subset of this body of work focuses squarely on the legal and political institutions and meetings that produce human rights laws and standards, examining the cultural and social precepts and expectations brought to bear on the drafting processes themselves. These institutions, it is often argued, form a technocratic, legalistic, "culture of rights" that is roughly analogous to ethnic cultures in that they are premised on shared understandings, maintenance of social boundaries through educational and professional requirements, and frequent interaction.

In conjunction with a focus on the social processes of human rights, anthropologists have built up an extensive corpus exploring the effects of political and structural violence and war on groups and individuals. An important part of the anthropological study of violence in conflict is to understand the cultural and social logic that shapes how violence is enacted. Research conducted on the conflicts in Rwanda and Sierra Leone, for instance, have demonstrated that violence is often not random or gratuitously grotesque, but follows a particular rationality. These studies offer a counterpoint to popular representations of non-Western conflicts as particularly nasty or barbaric by foregrounding how violence is expressed in a culturally and socially relevant manner and thus follows an instrumental logic, however unpleasant the result may be. Anthropologists have generally argued against totalizing interpretative models, suggesting that all conflicts are ethnic or between competing religions, and advocated paying attention to the multitude of cross-cutting social relationships of kinship, ethnicity, religion, nationality, and class that may be factors in the emergence of armed conflicts.

Other studies have emphasized the international dimension of ostensibly domestic conflicts, demonstrating how such conflicts are often embedded in global capitalist processes, fueled by the international trade in arms, drugs, and commodities, and exacerbated by corruption and the grinding economic inequalities between regions, countries, and groups. Other anthropologists have focused on the effects of

fear and violence on communities, foregrounding the effects of trauma and impunity on social attachments and civil trust and how cultural identities are shaped by the militarization of everyday life. Drawing on work in Guatemala and Northern Ireland and other countries and territories, anthropologists have approached political violence as one of the ways through which a government or alternate authority structure creates and maintains a particular order and may suppress some voices while legitimizing others.

The resolution of conflicts, peace processes, and the aftermath and remembrance of war have attracted considerable anthropological attention as well. Anthropologists have brought a range of perspectives to bear on these matters, ranging from the study of the juridical processes intended to punish perpetrators of war crimes and crimes against humanity (such as the international criminal tribunals for Rwanda and former Yugoslavia) to the commemoration of the victims of war and genocide. Truth and reconciliation processes, most notably the South African transition from apartheid, have generated a significant body of work in which anthropologists have scrutinized their underlying assumptions, most notably the assumption that societies are analogous to individuals and that speaking out would work as a therapy for the nation. A few studies have also examined how some grievances are made part of the official version of the peace processes and others shunted to the side.

War and violence are not always easily amenable to ethnographic analysis, however. The methodological challenges are numerous and include the difficulty of tracing processes spanning multiple locales and the difficulty of securing reliable information. Some anthropologists have also voiced concern about the ethical responsibilities of anthropologists in situations of conflict, noting that there is a shortage of anthropological studies of the perpetrators of human rights abuses but cautioning against seeming to morally justify these abuses. The paramount concern, however, is the personal safety of the anthropologist as well as the individuals or groups he or she studies and for whom he or she may be an advocate. The murder of Myrna Mack, a Guatemalan anthropologist who had advocated for the rights of rural indigenous communities, is a well-known example of the risks anthropologists may take when speaking up for a marginalized group in a context of violence.

Rights, Cultural Property, and Anthropological Research

Human rights are not just a subject of anthropological research, but as a body of norms and laws, a factor impacting the conduct of anthropological research itself. This impact ranges from general provisions applicable to everyone (freedom of movement, for instance) to sets of rights specifically concerning areas of traditional anthropological expertise, such as cultural rights and the rights of indigenous peoples and minorities. Both of these areas of rights have seen a dramatic expansion of late as the UN and the regional human rights systems are increasingly seeking to frame the rights of indigenous and minority groups not just as protection from discrimination, but as a right to have their cultural heritage protected and promoted. Cultural rights refer to an amorphous set of rights to both cultural identity in the sense of a way of life, ethos, or worldview and the material expression thereof, and the right to create and enjoy particular genres of what is often referred to as “high” culture, such as art or music. Cultural rights consequently butt up against a range of other rights, including the right to freedom of expression, rights to education, and intellectual property rights. This distinction is muddled, however, by the increasingly common adoption of a model of property rights to matters of the cultural heritage of indigenous and minority groups.

As the obligations of states to protect and promote aspects of minorities’ and indigenous people’s cultures are strengthened, anthropologists may find themselves caught between the requirements of research and their human rights obligations toward the people they study. There is an emerging global consensus that material culture or biological remains linked to a culture or nation should not be removed from that culture or nation except in particular authorized circumstances (such as on loan for a museum exhibit) or that where such items have already been removed (be it due to war, colonial conquest, or theft), they should be repatriated. Well-publicized disputes such as that over the Elgin Marbles (a series of reliefs removed from the Parthenon by an English nobleman, Lord Elgin, sold to the British government in 1816, and now on display in the British Museum) have generated an extensive debate as to what the grounds for repatriation should be: whether the return of a few archaeological items would set a precedent that would force many major museums to give up significant parts of their collections

and whether the retention of an artifact might be permissible if its return to the culture or nation would endanger it due to limited resources for its conservation or its potential to be resold on international art markets.

As a response to these concerns, many countries have enacted legislation intended to protect the rights of indigenous and other cultural groups to their patrimony. The Native American Graves Protection and Repatriation Act (NAGPRA) was passed by the U.S. Senate in 1990 and established requirements for the repatriation of Native American and indigenous Hawaiian items to their descendants and culturally affiliated groups, as well as a process for the claiming of Native American cultural items. While the anthropological community's reaction to NAGPRA and similar initiatives in other countries has been overwhelmingly positive, the resultant tension between the requirements of scientific research and the right to cultural patrimony has occasioned several disputes, such as that of the "Kennewick Man." The Kennewick Man is a skeleton found in the state of Washington, in 1996, with the potential to complicate our present understanding of prehistoric America. The discovery and efforts to identify the origin of the skeleton pitted Native American groups against anthropologists and other researchers (the very name Kennewick Man is itself contested). The former group argued that the skeleton was Native American and thus had to be repatriated to them as required by NAGPRA, and the latter group argued that the association between the skeleton and the Native American groups is not easily scientifically demonstrable and that the scientific right to study the skeletal remains for the benefit of the broader community cannot be limited by NAGPRA. The debate also implied an argument, ultimately won by the anthropologists, over whether or not oral traditions were equal to written sources of history and scientific findings in terms of their validity and reliability.

The protection of intangible cultural heritage raises similar questions of ownership and cultural property. Efforts by UNESCO and other groups to codify standards and obligations for the protection of cultural practices such as music and folklore (most recently, the 2003 Convention on the Safeguarding of the Intangible Cultural Heritage) seek to establish lists of cultural practices under threat and recommend measures to be taken by governments to prevent their disappearances. Anthropologists have noted,

however, that by seeking to preserve particular instances of cultural expression, one essentially makes that instance the paramount expression, contrary to our contemporary understanding of culture as fluid and negotiated. The process for deciding what practices will be singled out for protection by government is not always transparent and might conceivably be abused by special interests. The call for the safeguarding of intangible culture, moreover, entails a judgment of what culture change is desirable and what is not without providing any clear guidelines for making that determination. Finally, some anthropologists have expressed dismay over efforts to transform cultural practices into property that can be legally protected and exchanged as commodities (for example, the treatment of indigenous pharmacological knowledge as an intellectual property).

These concerns are weighed against the ethnographic reality of culture loss, where communities feel that their cultures are under siege from external pressures. Anthropologists and activists have also expressed concern over the phenomenon of "language death," or the decrease in the speakers of a language to a point where it is no longer used. Many of these worries are not new to anthropology, however. Early anthropology under Franz Boas and his students contained an exhortation to "salvage ethnography," or the recording of cultural and linguistic data for posterity, premised on the assumption that if linguistic and cultural diversity are diminished, humanity at large is poorer. More recently, the responsibilities of the anthropologist with regard to ethnographic data have become of increasing concern. The aforementioned epistemologically reflexive turn of the 1980s, mindful of anthropology's reputation and sometime collaboration with colonialism, was particularly concerned with how ethnographic authority is established, the collaborative nature of field research, and the ownership of ephemeral cultural data recorded by the anthropologist. While it is widely held that anthropologists are obliged to share the results of their research with the communities they study, the allocation of responsibility for data past that point is uncertain. The ownership of a recording of a performance, for instance, may be said to belong to the anthropologist who did the recording or to the informant who performed. Whether or not these kinds of cultural artifacts can or should be repatriated remains unclear.

Irrespective of the legal or scientific merits of these and similar discussions, some anthropologists have

expressed dismay over the adoption of a model based on ownership and property for the protection of groups' cultural heritage, as the presuppositions of that model are not necessarily appropriate for matters of cultural identity. These concerns include whether one can stipulate that a given artifact or practice is somehow necessary or important to the survival of a particular cultural practice and the underlying reification of a cultural group as an entity whose integrity is measured by the retention of material objects. Other anthropologists question whether an approach based on rights is efficacious and whether it may trap negotiations of culture in a legal framework and thereby distort them. These misgivings notwithstanding, most anthropological researchers are broadly sympathetic to the aims of NAGPRA and similar national and international efforts.

In addition to these cultural rights, anthropologists follow the same guidelines for research on human subjects used by other social and natural scientists. These guidelines overlap with well-entrenched human rights norms, like prohibitions on forced labor and the right not to participate in a scientific experiment without informed consent. These normative standards are given formal expression in national laws, university regulations, and professional codes of ethics and conduct. Accusations of violations of these and similar rights by anthropologists are rare, but a notable exception is the debate surrounding anthropological research conducted among the Yanomami (an indigenous group in Brazil and Venezuela). The controversy was sparked by a book by an investigative journalist alleging that the researchers, including several anthropologists as well as medical and biological scientists, had purposely started an epidemic as a scientific experiment. An inquiry into these charges would eventually conclude that they were unfounded, but the controversy nonetheless foregrounded the ethical responsibilities of anthropologists.

Episodes like that of the Yanomami are exceptions to the fertile interaction between anthropology and human rights and the numerous contributions made by anthropologists to alleviate specific human rights problems. Anthropological expertise has also been marshaled in support of forensic investigations into genocide and ethnic cleansing. The often rare cultural and area expertise of anthropologists is often called upon for political and legal proceedings such as asylum cases. Anthropology remains central to the effort to protect against the involuntary fading away of linguistic

and cultural practices, whether tangible or intangible. Finally, anthropologists often effectively speak out against abuse and injustice, drawing upon a rich legacy of commitment to tolerance and human rights.

HUMAN RIGHTS IN THE GLOBAL SOCIETY

You gain strength, courage and confidence by every experience in which you really stop to look fear in the face.

— Eleanor Roosevelt

Every day, year after year, women grotesquely disfigured by fire are taken to Victoria Hospital's burn ward

here in India's fastest growing city. They are in rows, wrapped like mummies in white bandages, their moans quieted by the pain-obliterating drip of morphine. Typically, these women, and thousands like them, have been depicted as victims of disputes over the ancient social custom of dowry and as symbols of the otherness of India, a place where lovely young brides are doused with kerosene and set ablaze for failing to satisfy the demands of their husband's families for gold, cash, and consumer goods that come as part of the marriage arrangement.

As European countries batten down the hatches against immigration, seen as a burden on welfare and a threat to national identities already blurred by globalization, illegal immigration is soaring.

"Welcome to Europe" says a sign on the western side of the bridge over the Bosphorus in Istanbul, Turkey, but the Europe of high incomes and generous welfare benefits that immigrants dream about is hundreds of miles west of here. For many, the road to it runs through the seething Istanbul quarter of Laleli.

Here, the seedy hotels are full of Russian prostitutes known locally as "Natashas," and the traffic in false passports that might afford entry to the European Union is brisk. Almost every day, newspapers are filled with accounts of discrimination, massacres, torture, or forced disappearances of political opponents. Horrors and tyranny are certainly not new in human history. The difference is that today there is a new parameter for assessing them: breach of this or that human right. This is an indubitable advance. Since 1948—that is, after the adoption of the Universal Declaration of Human Rights—all countries in the world, including those that had not gone through the long historical process of formation of the modern liberal-democratic state, have at their disposal an *international code* to decide how to conduct themselves and how to judge others. This is a code that not only has the virtue of *universal application* but also includes valuable principles in areas previously neglected by the constitutions of Western states. Previously, a state was accused of massacring an entire population; today, international norms talk of genocide, using this term with full awareness of its scope. Previously, it could be said that a state was torturing citizens; today, in addition to torture, international norms forbid any "inhuman or degrading treatment, or punishment." Previously, all one could do was denounce certain governments for neglecting the interests of their population; today, they can be

accused of breaking the international rules providing for the right to food, the right to decent housing, the right to a healthy environment, and so on. Looked at properly, this does not mean merely that new definitions and a new "labeling" system are available to states and individuals; the international rules on human rights impose modes of behavior by requiring governments to act in a certain way and at the same time legitimize the complaints of individuals if those rights and freedoms are not respected.

The areas of human rights protected at world level has become quite broad. First, it includes *civil liberties*. These consist primarily of the "free space" that every government must guarantee the individual by not interfering in a certain private sphere: the right to life and security, to privacy, to "family life," to private property; the possibility of expressing one's opinion freely, of practicing a religion or not, and of peaceful assembly. Civil liberties also cover the state's obligation to articulate its structures in such a way as to guarantee a minimum of respect for the human person, as well as full justice in cases of abuse: the right not to be subjected to arbitrary rights to a fair trial. The international community further enforces *political rights* (the possibility for the individual to contribute, alone or in association with others, to the life and action of government: the right to associate, to form political parties, to take part in elections, to be elected to the various state offices, and so on). Also recognized at international level are *economic and social rights*. These are entitlements that the individual has vis-à-vis the state, in order to obviate social inequalities and economic imbalances, and to limit disadvantages caused by nature, age, and so on. By contrast to the other rights, the state is not bound to meet these entitlements all at once, but may see to them gradually, taking account of the economic and structural problems it has to face. In addition to the rights belonging to individuals, international norms also cover those of *minorities* and of *peoples*. Peoples in particular have, on certain conditions, the fundamental right to self-determination, that is, the right both freely to choose their own international statutes and to adopt the type of government most suited to popular aspirations.

If, then, every day some state is denouncing violations committed by other countries, if the media lend their support to this denunciation (or more often draw attention to facts and events that have frequently taken place in silence), all this is due *also* to

the existence of this broad set of international principles, which function like a kind of decalogue—to be observed and reinforced. All the inhabitants of the world benefit from the same principles and can voice their protest when they seem them violated. Human rights are an ideological and normative “galaxy” in rapid expansion, with a specific goal to increase safeguards for the dignity of the person.

The Emergence of Human Rights on the World Stage

The traditional pattern of the nation-state begins with the Peace of Westphalia (1648), and its evolution continues to this very day. It was after World War II that the notion of *peoples and individuals do not count* came to an end. Prior to World War II, individuals did not exist, being absorbed and overshadowed by the sovereigns and the sovereign states. Frequently, they pass from one sovereign to various rulers. Individuals are less overshadowed, but only insofar as they constitute emanations of their sovereigns. The citizens of a state who travel abroad to settle, trade, set up industries, or simply visit the country remain under the protection and aegis of the nation-state; to it the state of residence has to account if its authorities infringe the foreigners’ rights, take away their goods, or treat them in an arbitrary fashion. Individuals thus become beneficiaries of a series of international legal standards—those on protection of foreigners—which of course regulate only relationships among sovereign entities but end up safeguarding interests and the property of citizens of each one of them. These individuals, however, remain mere beneficiaries of those standards, as is shown by the fact that if their rights and interests are injured by a foreign state and their own state decides not to intervene through diplomatic channels or not to start legal proceedings before international arbitrators (set up before the controversy), they can do nothing against their authorities’ failure to act. In this case too they remain pawns in the game among the powers, advanced or sacrificed according to momentary whims or, at any rate, the political inclinations of the various sovereigns. After World War II, another great phenomenon took place in the international community: the launching of a *natural-law doctrine of human rights*, directly impinging upon the relationships between each state and its citizens.

Human Rights

Distinctions among various categories of human rights, civil, political, economic, social, cultural, individual, collective, positive, negative, first, second, or third generation, and so on are often misleading and rarely result in greater protection for individuals or groups. Indeed, the most common purpose for identifying such categories is to deny the status of *right* to one or more of them, rather than to expand international or domestic protections.

Conflict and tension are inherent in society; so are differences in individuals and cultures. One goal of the state, under the most fundamental of international human rights’ norms, is to eliminate discrimination, not to destroy all differences. Recognition of the right to personal autonomy and group identity is essential to ensure that the principles of self-determination, participation, and tolerance are allowed to flourish. How is the United Nations situated in order to better help women whose rights were and are being violated?

In relation to the world’s women and equal opportunities and pay for public sector employment, unequal opportunities in public education and discrimination by private bodies abound. Should not all countries, regardless of resources or religious/cultural and other beliefs, be required to address assaults on women’s rights, such as harassment of women in detention, failure to enforce laws prohibiting bride burning, and other forms of domestic violence, toleration of female circumcision and other mutilations, and maintenance of inequitable laws regarding marriage and succession rights? Meaningful progress in promoting women’s rights required emphatic and authoritative responses to those and other questions. In developing responses, the committee on the elimination of discrimination against women helped make a convention on the same a fact, and entered the convention into force in September 1981. As of March 1988, 94 states had ratified it. *Discrimination* is defined as “any distinction, exclusion or restriction made on the basis of sex, which has the effect or purpose of impairing or nullifying the recognition, enjoyment or exercise by women, of human rights and fundamental freedoms in the political, economic, social, cultural, civil or any other field” (Article 1).

The Commission on the Status of Women has begun to grapple with allegations of consistent patterns of discriminatory practices. It has yet to undertake a study on the relation between convention rights and Islamic

Law, despite the obvious importance of the issues to its monitoring work.

The East Asian discourse on human rights has been growing since the 1993 Bangkok Declaration on Human Rights, when parallel regional networks of governments and nongovernmental organizations (NGOs) first appeared. It has been spurred by a combination of factors. First, political opening allows for the growth of civil society as educated citizens confront economic development in an era of intense global competition. Next, East Asians are seeking out local attachments to recover a sense of belonging and trying to come to grips with the postcolonial identity, while at the same time identifying with larger, international human rights movements. Third, new social, political, and economic tensions come with greater income stratification and the breakdown of the community and the safety net it provided. Finally, networks of people throughout the region with shared human rights concerns are continually expanding. The new human rights discourse is also a reaction to the increasing pressure on East Asian governments that comply with international human rights norms. The pressure comes from an international community that has heightened expectations for a part of the world that has become irrevocably integrated into global markets. When Asian officials and their supporters want to challenge Western-style civil and political freedoms, they use the term *Asian values*.

The citizenship rights of women in a modern Islamic state in East Asia have to be explored in the context of Islam, particularly present-day Malaysia and Indonesia. Internationally, as far as human rights issues are concerned, Islam frequently gets very bad press, sometimes unfairly, but all too often deservedly. Yet actions taken in the name of Islam are often not based on true Islamic principles. Islam has the capacity to yield a notion of universal human rights, the idea that, by virtue of their intrinsic humanity, transcending all cultural and historically conditioned differences, people share certain essential entitlements. In the West, the development of the modern nation-state is generally equated with secularization. But in East Asia, the development of the modern nation-state over the past 30 years has demonstrated that often the influence of religion has grown as the consolidation of the nation-state takes place. A striking example of this is Islamic resurgence. The postcolonial development of most Muslim countries saw increasing tension between the adopted social and

political order and the renewed efforts of many of their citizens to define and strengthen their Islamic identity.

The confrontation has accelerated various forms of “Islamic” discourse about human rights. Contemporary Muslims, like followers of the other two great Abrahamic religious traditions, Christians and Jews, have shown a notable concern for human rights that is not grounded in any borrowed “Western model.” Instead, they have attempted to demonstrate that a human rights culture comes from the Qur’an and the teaching of the prophet Muhammad. This drive to reclaim for Islam a vision of human beings and a practice of law and politics that sustains an Islamic version of human rights has resulted in extensive writings by contemporary Muslims on the relationship of Islam and human rights. Yet the vast social changes that span the time between the establishment of the first Islamic community and the emergence of the contemporary world order require a creative and historically sensitive interpretation of that model that is not often reflected in the literature. Most Islamic writings are dominated by two problematic positions, which are in fact not so far apart in terms of their implications for contemporary human rights principles.

On one side are Muslims who maintain that Islam embraces human rights standards similar to Western-derived international human rights standards. They advocate integrating Islamic rules and concepts with internationally recognized rights to bring them into conformity with Islamic standards—the rules of Shari’a’s. However, close scrutiny of this approach reveals various levels of ambivalence about the concept of rights. It is fraught with reservations and restrictions on a range of rights and freedoms, especially as they pertain to women and non-Muslims. At the other extreme are those Muslims who claim outright that current human rights concepts and standards (especially those incorporated within prevailing international human rights documents) are completely alien to Islam and incompatible with Islamic law as they interpret it. Between these poles lies a precarious middle ground—a space within which some of the most creative and inclusive Islamic sociolegal thought is now being created. However, like courageous and innovative thinking elsewhere, such sociolegal modernism is far from dominant within the Islamic world, especially in its Middle Eastern heartlands. It is a discourse propagated in the

main by Muslim intellectuals, many of whom are now forced to live in exile in the West for advocating their ideas. Although their positions may vary to some extent, the common thread among these intellectuals is that they advocate a critical reexamination of exegetical and jurisprudential texts as well as, whenever possible or pertinent, a reinterpretation of Islam's foundational religious texts.

Muslims advocating equal rights for women have emphasized in their discussion the problematics of interpretation of texts and, from those interpretations, of the contemporary codification of Muslim laws on the rights of women. The call for a review of the long-accepted juridical opinions and interpretations established during the classical age of Islam also characterizes many contemporary movements promoting the rights of women and of non-Muslims coexisting in a predominantly Muslim country.

Human Rights as a Universal Concept in Islam

Two main issues confront modern Muslims considering how to apply their own distinctive perspective to existing international human rights. The first is the prevailing Shari'a's definitions of human and citizenship rights. They must consider the position of any special category or subset of acceptance of the rights of humans simply by being humans. This awareness is by no means alien to Islam. It is grounded in the Qur'anic notion of a common human ontology (*fitna*) and couched in an Islamic idiom of moral universalism that predates much of the Western discourses about human rights. It is thus doctrinally a part of the Qur'anic worldview itself.

The challenge to contemporary Islam and to Muslims, especially the new traditionalist ideologues, is to revive and embrace that which is their own. It is nothing more than a challenge to begin to see humans, all humans, in the way that their faith insists that God/Allah sees them.

Second, Muslims contribute their own modern and Islamically appropriate conceptions of equal social relations between men and women to the human rights discourse. Here again, Qur'anic conceptions of the rights and duties of men and women in the family—to own and manage property, and to participate in public life and hold public office, for example—provide the basis for a far more enlightened and egalitarian view of gender relations than the regressive ideas that are

currently offered, misleadingly, in the name of Islam by fundamentalist Islamists the world over.

Until these two main issues are clearly defined, human rights instruments and their moral foundations, derivatively Western in their origins and history, can be neither embraced wholesale nor summarily rejected by modern Muslims. Only after a critical reevaluation of their Islamic heritage and the acceptance of an underlying common humanity can progressive Muslims decide in what ways and to what extent they should accept, reject, modify, or renegotiate the stock of concepts and ideas that are now offered as the basis for a universal concept of human rights.

Citizenship Rights and the Position of Muslim Women

With respect to the states of Muslim women, although it is true that they have full legal capacity under Shari'a in relation to civil law and commercial law matters, in the sense that they have the requisite legal personality to hold and dispose of property and otherwise acquire or lose civil liabilities in their own independent right, Muslim women do not enjoy human rights on an equal footing with Muslim men under Shari'a.

According to An-Na'im, most of the published expositions of human rights in Islam by contemporary Muslim scholars are not helpful because they overlook the problems of slavery and discrimination against women and non-Muslims. Muslim women scholars, on the other hand, have mainly highlighted those verses of the Qur'an that are consistent with human rights standards. But a major problem still remains: Some crucial verses exist that are inconsistent with or even contradictory to universal human rights conceptions. An-Na'im has suggested that the only effective way to achieve sufficient reform of Shari'a in relation to universal human rights is "to cite sources in the *Qur'an* and *Sunna* which are inconsistent with universal human rights and explain them in historical context, while citing those sources which are supportive of human rights as the basis of the legally applicable principles and rules of Islamic law today." A major, often ignored, problem with respect to rights is that the "Shari'a-minded" "traditionalist," or "fundamentalist" recodification of modern state laws redefining people's rights, especially women's rights, affects democratic participation and citizenship rights as well as personal rights. Yet this proposed

Shari'a-based recodification is promoted by and also borrowed and imitated from countries, especially in the Middle East, that typically lack any articulated notion of citizenship rights. They are states with regimes but without citizens or "civil society." They invoke and uphold the adequacy of conventional Islamic views of the purely personal status rights of women and non-Muslims. By this maneuver, intentionally or by oversight, they set aside or rule out any consideration of the broader social, civic, and political rights and full legal rights of women and non-Muslims as equal citizens of the state.

No wonder that the Islamist ideologues promoting this Shari'a-based recodification can blithely dismiss the disquiet voiced by modernist Muslim critics with empty assurances that "all will be well" under the new Islamist ideologues because they have no modern experience of citizenship. Such moral and intellectual foundations are well beyond the reach of the ideologues' sociolegal consciousness. This draws into question how appropriate their ideas and agenda are, arising from their own limiting circumstances, as a basis for modern social policy and legal reform under different, less restricted conditions. Why should countries like Malaysia, which are already launched on a trajectory toward modernity, with modern notions of the nation as a community of people sharing citizenship rights, accept the elaboration of modern notions of citizens' rights from religious ideologues and developmentally deadlocked nations that lack any modern understanding of citizenship?

That such "Islamic" ideas, with their yearning for an unrealized utopian ideal, should be able to exert a powerful appeal among social groups that see themselves as excluded from or victims of development is not surprising. But it remains troubling to modern Muslims sensitive to the centrality and resonance of the issue of rights in both Western and Islamic historical consciousness and civilization. What especially concerns modernist Malaysians is the apparent readiness of some of their national leaders, who at the overtly political level directly oppose the "Islamist" agenda and the parties advocating it, to accommodate these tendencies and capitulate piecemeal to demands in such areas as the recodification of modern state law, especially in areas most affecting women.

In many Islamic societies today, there is a tendency to define the rights and obligations of citizens on the basis of gender and faith. This mind-set reflects the popular view that the typical citizen is a Muslim male.

What is missing from this view is a recognition of the rights of human beings simply as human beings, which, as stated earlier, is a Qur'anic notion. This gap between the ethical principles of the Qur'an concerning gender equality and the kinds of retrogressive and male-centered interpretations that have been codified into Shari'a law provides a challenge for modern Muslim women's pursuit of equality and respect for their rights.

The Concept of Change in Islamic Society

As today's Muslim nations modernize, the socioeconomic circumstances of the majority of Muslim women will inevitably change. Many Muslim scholars assert that the way to move forward is for Muslims to develop (or recover) the imaginative ability to grasp such fundamental change. I say "recover" because from the inception of the history of Islam, Muslims have always held, at least theoretically, that change (change in people and in society) is possible, part of the human condition itself. But while the Muslim worldview has encompassed this possibility as a matter of principle, most Muslims themselves have lost the practical ability to face, understand, and master change.

There are many examples of a Qur'anic foundation of the concept of change; the Qur'an, in taking humankind beyond the age of ignorance (*jahiliyya*), oriented human thinking toward the possibility of change. Early Islam also incorporates the idea of change through migration or *hijra*, a movement not simply from one place to another (Mecca to Medina, in the paradigmatic instance) but from one social and moral plane to a higher one. Muslims have evolved from being one community, a part of the city-state Media, to become part of an empire, a political identity that extended well beyond a state by the time of the Abassid Empire. From a state with a central authority in Damascus or Baghdad emerged a polity with many autonomous governments and distinct political entities. In other words, change has been a constant of Muslim existence.

Islamic law itself has evolved along with changing circumstances, in part through the operation of *ijtihad*, or informed critical reason, which applies Islam's broad legal principles to emerging social and historical realities. Yet despite these possibilities for flexibility and dynamism, Islam has become stagnant. Many Muslims in Malaysia and elsewhere are always ready

to blame colonialism for this cultural stagnation. Whether it is colonialism itself that is at fault or, as Malek Bennabi suggests, the readiness to accept colonialism (or its twin phenomenon *colonisibilite*, the domination of the mind by alien ideas and a habituation to passivity toward alien cultural domination) is another debate. In any case, Muslims are not heirs to a history of stagnation that must be overcome, and Muslims need to regain a belief in change and in the ability to manage it intelligently, to pursue independent agendas rather than to capitulate to those of others. In this context, modern Muslims, especially in countries such as Malaysia that lie outside the culturally Arabic heartlands of Islam, need to be wary of acquiescence to a new colonization, one carried out by traditionalistic Islam misunderstood as the trans-historically essential Islam. What is required is a calm and reasonable debate on the issue of historicity and change in the Islamic heritage of contemporary Muslims. This in turn requires modern Muslims to act upon a basis that is historically informed and feasible, not historically and religiously confused.

A necessary part of this discussion turns upon understanding what is divine in the Shari'a and what, in the scholarly tradition interpreting it, is of human origin. What is divine is the *nass* of the Qur'an or the "word of Allah," the text and all its intentions and purposes. The act of interpreting the text and deriving its meaning and intended purposes is human, especially the methodology of interpretation devised by the experts of interpretive legal reasoning, the *fuqahas*. This means that various methods of interpreting the text through the use of critical reason (*ijtihad*), analogy (*qiyas*), and consensus (*ijma*) can be reassessed and reevaluated. Modern Muslims are entitled to further develop those corpora of interpreted material. The choice is between futility and creativity, between attempting to impose archaic and limited legal understanding upon the present and seeking to understand the history of Islamic civilization in its entirety so that modern believers, members of an interdependent humankind, may act authentically as well as realistically and effectively as Muslims upon the stage of global history.

Gender Equality and Qur'anic Islam

The Muslim traditionalist position on women's rights rests heavily on the argument that Islam recognized no notion of gender equality. This assertion is based

on two theological claims: first, that because at the time of creation the female was created from a man's rib, she is therefore in her origins derivative, and thus men are inherently superior to women, who exist for men's use. The second claim is that men are *qawwammun* ("have responsibility") over women, a claim based on the traditionalists' preferred interpretation of a key Qur'anic verse. Thus it is the woman's role to provide for the man's needs and continued reproduction through loyal service in the domestic realm. This claim finds its expression in the interpretation and emphasis given by traditionalists to the Qur'anic injunctions that "your woman are a tilth for you to cultivate, so go to your tilth as you will."

The theological foundations for this imposition of female subordination have been critically and effectively challenged in recent years. For example, Fatima Mernissi of Morocco and other Muslim scholars from Egypt, India, Pakistan, and the Sudan have provided cogent arguments that in principle and intention, Islam actually promotes gender equality. The common assertion of Muslim modernist scholars is that Islam is a liberating religion that uplifted the status of women and gave them rights considered revolutionary 1,400 years ago. Their arguments rest on the shared assertion that none of the Qur'anic verses that speak of human creation make any mention of women as an inferior or derivative being. "There is absolutely no difference in the value given to the creation of woman and the creation of man. Biological differences do not mean that women and men are not of equal value." Riffat Hassan, for example, has shown that "the story of the rib" was derived from the Old Testament, which was later absorbed in *hadithi* literature.

The economic responsibility for women that is mandated here must be related to "the occasion of revelation" of that verse, the need to secure the economic welfare of women. This included especially widows and divorced women of the clan-based patriarchal society of the prophet Muhammad's time, when women lacked full autonomous economic participation and enjoyed only half of the inheritance rights of men. But this verse, the modernists argue, cannot be understood as instituting a general subordination of women, because the Qur'an and Sunna at the same time recognized women's equal capacity to fulfill other roles—social, intellectual, and spiritual.

A common feature of the counterarguments provided by these critical scholars is their persistent questioning of the historical bases of the standard

male-supremacist and orthodox interpretations. They demonstrate that what was generally enshrined within and elaborated through the evolving Islamic legal culture failed to distinguish clearly between conservative Islamic social tradition and the normative Islamic legal principles expressed in the foundational texts.

Reconciling Local Culture and the International Human Rights Regime

Acceptance of the International Convention for the Elimination of All Forms of Discrimination Against Women—the United Nations organization’s women’s convention (CEDAW)—has been problematic in countries in which Muslim law is applied. Certain influential Muslims resist CEDAW purportedly on Shari’a grounds, and their critique must be addressed at a fundamental level.

There are simply no shortcuts around these obstacles. In the long run, before instruments such as CEDAW (or even recent domestic laws that provide for rights of women) can have a positive impact in these societies, women and women’s movements will have to ensure, first of all, that the sources of all the various forms of subordination that arise from cultural and religious traditions are identified. Only then can they be differentiated from what Islam enjoins and be exposed to thoroughgoing criticism, leading to their rejection and abolition, precisely on the grounds of what Islam enjoins.

The Qur’an and the Universal Rights of Humankind

This underlying notion of rights and freedom open to all faithful believers, and to all who may yet come to recognize the supremacy of Allah (that is, all of humankind), is not dissimilar to modern notions. According to the Qur’an, a Muslim person who suffers oppression and does not do anything about it is a sinner. Such a person is encouraged to migrate elsewhere if he or she is unable to fight against an oppressive system. The Qur’anic term *ibn al-sahil* refers to someone who is forced to move from place to place in order to seek a more peaceful life free from oppression. That is, to endure oppression involves a double violation of divinely ordained human nature and autonomy: by the oppressor and by the victim. Implied in this is a profound affirmation of human

freedom, dignity, and autonomy—and of the human as a rights-bearing being.

Apart from the concept of *fitna*, which refers to humankind as an undifferentiated whole, the Qur’an also speaks of human dignity. The Qur’anic term “descendants of Adam” does not just refer to Muslims, or to a particular group of people, but to all humankind. “We have conferred dignity on the descendants of Adam” (*Al-Isna* 17:70). There is also the notion of diversity in the one humankind. On the basis of their differences, humans are to come together not just in a superficial way but in profound human and cultural contact. This notion of *umma* refers to humankind in its entirety and diversity, and human beings are given the right of religious conscience, an entitlement to their respective religious views and commitments. This is the capacity for spirituality that all humans share. It is not a Muslim monopoly but is immanent in every human heart and mind according to the Qur’an. As humans we not only enjoy a generic equality but also an ontological common ground.

The struggle for human rights, especially women’s rights, in Muslim countries is complex. It involves the validity and hegemony of certain religious interpretations over others, gender bias, patriarchy, and the politics of identity. The often heard criticism that Western conceptions of women’s rights and gender equality contradict Islamic principles of gender relations can no longer be accepted at face value.

Yet because of the pervasive influence of the literalist Islamic resurgent movements in many Muslim countries, women and women’s groups struggling for recognition of their rights, both personal and public, have to make common cause with whatever modernist religious impulses are to be found in their own societies. By doing so they not only enhance the Islamic legitimacy of their cause, but they also thereby ensure that their endeavors are recognized as an integral part of the overriding question facing contemporary Islam: the attainment, based on the cultural and ethical foundations of Islam, of modernity. Negotiating space for public debate of the many issues relating to women’s rights and freedom is a task that Muslim women can most readily achieve not through a solitary, separatist struggle but in concert with other Islamic modernists and human rights activists who recognize their cause as an inescapable public concern for 21st-century Islam.

The view of some human rights activists that women’s rights movements are better served by utilizing the “secular” approach—one that bases its

arguments in the supposedly universal rule of law and democratization—is not at all pragmatic nor as easily implemented as its proponents claim. The experience of many women's groups operating in Muslim countries these past two decades demonstrates that in their daily battles a great deal more progress is achieved by working within their religious and cultural paradigm. This gives Muslim women's movements a distinctive character when compared to Western women's movements. Muslim women's rights activists have to employ a wide variety of approaches in their project to advance the status and rights of Muslim women. Their ideas, conceptions, and recommendations for rights and social emancipation must be religiously and culturally informed as they confront the challenge from their own religious, political, and community leaders, male or female. A common thread between Western and non-Western women's movements is found only within a social fabric or against the background of persistent gender bias in the assertion of modern-day patriarchal ideologies.

The path for human rights does not run smoothly or straight; every day we stumble against the irrational, and reason is pushed to one side and rights are trodden underfoot. Many of the forces that oppose human rights irrespective of gender are authoritarian regimes, theologically based regimes, heavy-handed and all-inclusive government structures as well as private groups (think of the Taliban) that treat defenseless and innocent people with ruthless violence. All those who belong to such authoritarian structures or violent private groups of whatever ideology refuse to allow anyone to question or threaten their aggressive impulses and lust for power. The faint voice of human rights can hardly be heard over their clamor.

What, then, can be done? As we all know, Rome was not built in one day, and it will take more than a day or a year to ensure respect for human rights; the time required is long. The United Nations's protection of human rights resembles such natural phenomena as earthquakes, glaciations, climatic changes, all of which happen beyond a single life span and can be measured only in terms of generations. As the third millennium has begun, the United Nations's human rights agenda has picked up speed through the making, among other international venues, of the International Court for Crimes Against Humanity.

It is hardly surprising that human rights should take so long to become established. Though not a religion, human rights do possess many of the characteristics

of the main religious faiths. Centuries elapsed before the great religions began to expand; they were beset by obstacles, persecution, and a categorical refusal to accept their tenets. Yet, in time, they came to dominate the minds of men and women and to condition the behavior of people and states, generation after generation. The essential precepts of these religions were trampled underfoot by opponents and followers alike. Day by day the most sacred principles were violated; nevertheless, they continued to expand. All this is true of human rights, which many states habitually regard; yet they stand out as one of the great forces of natural law. To open people's minds, to illuminate the straight and narrow paths that lead in the right direction, it is important to ensure that the wells of public opinion are not poisoned by people becoming inured to authoritarianism and bullying.

HUMAN VARIATION

Human variation, historically a topic of much opinion, debate, and fallacy, is ruled today by deoxyribonucleic acid (DNA) technology that was absent from early classification systems. Before the onset of European exploration in the late 15th century, it was believed that humans were descended from a single pair and should not be placed into different categories as other animals were. However, the discovery of diverse cultures on different continents prompted scientists such as Linnaeus, Buffon, Blumenbach, and Cuvier to distinguish *Homo sapiens* by physical and cultural characteristics. Carolus Linnaeus, the first of these scholars, added temper, behavior, and dress to the already traditional division of skin color. Comte de Buffon, the next scientist to describe the human “race,” did so by categorizing different peoples by their geographic location. However, Buffon did not separate people into different species as Linnaeus did. In 1781, Johann Friedrich Blumenbach moved away from cultural traits altogether in his classification system and the limited set of physical characteristics he described were assumed to be finite for five varieties of people. Baron Georges Cuvier condensed these groups even further into basic “white,” “yellow,” and “black.” As one of the last classification scholars, Cuvier moved to eradicate the “Great Chain of Being,” which placed humans (unsurprisingly, Europeans) at the top of the animal hierarchy.

In the mid-19th century, scientists and anthropologists began to use a different approach to the question of human variation by quantifying observed physical characteristics. This was done through

anthropometry, the measuring of the body and body parts, particularly skulls, and noting variation between supposed ethnic groups. Samuel Morton measured skulls, and his conclusions are now believed to reflect his own stereotypes about certain groups of people. The cephalic index, a construct of Anders Retzius, was also used to compare different groups of people by cranial measures, which placed them into two categories: dolichocephalic and brachycephalic. However, one of the problems with craniometric analyses is that people from extremely different geographic locales may show similarities, giving questionable basis for division.

The number of “types” of people, however, lingers in a state of disagreement over characteristics that define a “race.” Thus, there have been many different definitions of the race concept. One of the broadest and currently accepted of these definitions was suggested by Huxley and Haddon in the 1930s and is the replacement of the word *race* with the term *ethnic groups*. The most conclusive definitions emphasize that the human species is polytypic, with different features loosely corresponding to certain geographic areas. There are three main ways that these differences come about: environmental adaptations, population genetics, and migration.

First, there are adaptive environmental traits unique to certain locales. Perhaps the best documented of these is sickle-cell anemia, an inherited disease in which red blood cells that are normally disk shaped are crescent shaped. The sickle-cell gene is common in Africa because it serves a distinct selective purpose. Those who carry one copy of the gene are resistant to malaria, a mosquito-borne illness. Those who carry two copies of the gene, however, have sickle-cell disease (SCD) and rarely live to reproductive age. Because of the pressures malaria places on those who live in high-risk areas such as Africa, populations in those environments have adapted and now possess a genetic trait indicative of their ancestry.

Sickle-cell anemia is an environmental adaptation that cannot be observed externally. The largely misinterpreted concept of skin color, however, can be. The rate in which melanin (a skin pigment) is produced varies with different skin types. Melanin levels are higher in darker-skinned people and lower in fairer-skinned people, and this variation is found latitudinally. Those living in lower latitudes have darker skin, where the abundance of melanin helps block harmful ultraviolet radiation. The lighter skinned are found in higher latitudes, where a lack of melanin allows more sunlight

Source: Photo provided by www.downtheroad.org, The Ongoing Global Bicycle Adventure.

to be absorbed. More sunlight means greater processing of vitamin D, a vitamin necessary for strong bones.

Along with environmental adaptations, population genetics is another way to explain human variation. In all organisms, the foremost means of achieving variation is through genetic mutation, specifically point mutation. Point mutations occur when a single nucleotide base is added, deleted, or replaced. If the mutation is advantageous to the organism, it will be passed on via natural selection. The aforementioned example of sickle-cell anemia is one such instance. It is probable that a human cell thousands of years ago underwent a mutation that produced the sickle-cell gene, consequently providing malarial immunity. Those individuals without a copy of the sickle-cell gene may have contracted malaria and died without producing their full potential of offspring at a higher rate than those that did have a copy of the gene. In contrast, people with one copy of the sickle-cell gene did not die of malaria and probably still retained full reproductive abilities, thus passing the gene on to offspring. Over thousands of generations (and malaria outbreaks), the frequency of the sickle-cell gene increased.

Finally, the third means of producing variation in humans is through migration and genetic drift. Over time, humans have always traveled, taking their varied gene pools with them. This means that people mated with people from other populations with different sets of genes, increasing genetic variation. The opposite, genetic isolation, can occur as well. A product of catastrophe or new habitation, isolation produces less variability within, but more variation between, populations.

Therefore, although there are several mechanisms in which human variation occurs, overall they are insignificant. During the recent mapping of the human genome, it was found that the DNA between any two individuals is about 99.9 percent identical. Hence, the concept of “race” based on individual physical variation has been rendered inaccurate, and scientists have in essence given up on a once popular notion.

HUMANISM, EVOLUTIONARY

Evolutionary humanism is a philosophical point of view centered on human interests and values in the context of natural selection and additional forces of evolution. Evolutionary humanists have called attention to the unity of the body and the mind, human continuity across populations and with other life forms, and natural instead of supernatural explanations. Evolutionary humanists often have human welfare and social reform in mind as an ultimate benefit of their scholarship, following philosophical traditions of humanism.

Humanism, in philosophy, is an attitude that emphasizes individual dignity, value, and self-realization through reason. Evolutionary humanism similarly appreciates individual differences and the implication of heritable variation across generations. Evolutionary humanists look at cooperative strategies in terms of individual and inclusive fitness benefits and are generally critical of unilineal social evolutionary arguments. Evolutionary humanists are concerned with the development of idea and moral systems through time and the relationship between art and the evolutionary process.

A basic premise of humanism is that people are rational beings who possess within themselves the capacity for truth and goodness. Evolutionary humanism

also assumes rationality in selection of adaptive traits and behaviors. Cost-benefit analyses are often made by evolutionary humanists in order to test hypotheses about factors involved in the evolution of traits. Truth and goodness are but one possible outcome, however. Evolutionary humanism must also include under study the development of malevolent human behaviors, such as ethnocentrism and warfare, and apparently maladaptive traits, such as drug abuse and celibacy.

Julian Huxley (1887–1975), grandson of Thomas Henry Huxley (Darwin’s “Bulldog”), was an innovative thinker in early evolutionary humanism. Huxley explored the relationship of human culture and its relationship to genetical evolution. For Huxley, evolution was directional in the sense that greater variety, complexity, and specificity of organization occur, albeit amidst evolutionary dead-ends. He applied this to analysis of idea systems and found that some idea systems might be potent and perpetuate even if inaccurate, giving examples such as the predictions of Marxist-Leninist theory regarding the state and the alleged supernatural benefits of human sacrifice by the Aztecs and resulting failure of their socioreligious strategy. Some of Huxley’s ideas related to culture as an instrument of human evolution have been modeled in contemporary dual transmission theory. Idea systems may change to an extent that they do not fit the developing conditions of human life (for example, frequency dependent and runaway directional selection). Huxley suggested that the scientific investigation of the human “psychosocial sphere,” considering observable historical and biological processes, would lead to the construction of a new, open-ended framework of comprehension. Huxley’s emphasis on the unity of the mind and body, such as his discussion of the function of emotions, is a precursor of evolutionary psychology.

A recent application of evolutionary humanism in anthropology is *Biopoetics: Evolutionary Exploration in the Arts* (1999). In this volume dealing with literary and visual culture, the authors explore inherited influences on aesthetic preferences, from body decoration to ecstatic states and science fiction. One revelation of this collection of evolutionarily minded analyses of literature and art is the surprising degree to which ancient and classic art reflect humanity’s evolved tendencies, predispositions, and concerns.

HUMANISM, RELIGIOUS

Within the discipline of anthropology, the subfield of humanism focuses on reason, logic, and scientific explanations for human existence, being skeptical of purely religious interpretation. Proponents of this approach, such as T. William Hall, in the text *Religion*, state, “This interpretation of human existence dispenses with belief in the supernatural, considers the good of humanity on earth the supreme ethical goal, and applies the methods of reason and science to solve human problems.” Following this same logic, Miles Richardson, in the *Encyclopedia of Cultural Anthropology*, adds that humanism “emphasiz(es) scholarly reading, as opposed to divine revelation, as the path to knowledge.” Religion is then a construct of the human mind, not an unknowable fact.

It is a construct capable of scientific exploration, hypothesis testing, and theory verification.

Anthropologists who study religion from a humanistic perspective would include such notables as Raymond Firth, Edmund Leach, Joseph Needham, Mary Douglas, Clifford Geertz, and Ernest Gillner. They apply a rationalist approach to the study of religious values, actions, and beliefs. Their approach to religion is as a cultural system that exists and can be rationally explored and understood. Religious systems are a part of a society’s total tapestry, a social reality that is constructed and explained, using the same methods and theories as the culturally constructed systems of politics, economic, kinship, subsistence, and art. When anthropologist Clifford Geertz writes in *The Interpretation of Cultures* that “religion is humanity,” this statement can also be stated in the reverse: “Humanity is religion.”

A religious humanistic approach to anthropological cross-cultural research can be described as being

anthropocentric (human as center of existence). Existence external to the individual or group is viewed as not being constructed and maintained according to a divine supernatural plan, with rewards and punishments for various thoughts and deeds, coupled with the perpetuation or violation of specific culturally predetermined, etiquette-established guidelines. Religion, as a necessary human cultural construct, is open to logical realistic explanation, using guidelines that judiciously explain fundamental shared human dilemmas, associated with basic everyday existence. Searching for answers to what cannot be explained by contemporary science in times of fright or confusion reinforces the need for religious beliefs. Religious explanations are provided to offer answers to the basic questions of life that science currently cannot. What is existence? Why do I exist? What is the universe? Why do things beyond our control happen? Why do we have to suffer? Why death? What is the relationship of humans to other species? The humanists would acknowledge that these cannot be answered but that the search for concrete rational explanations is a more worthwhile and potentially gratifying endeavor than the passive acceptance of religious dogma. They believe that it is possible to eventually discover reasonable and logical explanations for phenomena or at the very least believe that exploration remains open-ended and tentative to allow for additions of new factual conceptualizations. Religious practices and scientific explorations are believed to be complementary.

Religion from a culturally based, humanistic perspective has a strong cultural relativist approach. Each society constructs its own unique approach to religion, depending on its own unique and dynamic physical and social environment. There is a continuing desire to maintain existing functional cultural order and also to attempt to restore equilibrium in the inevitable times of chaos. Anthropologists search for the unique social qualities and attempt simultaneously to tease out the individual social threads from the larger tapestry of life. Each thread represents a different but complementary component of religious life: belief systems, functions and structures of myths and legends, use of symbolic objects and language, rituals including offerings, prayers, sacrifice, feasts, and causes and motivations for change. The expectation would be that morally based religious factors would necessarily vary across time and space in a dynamic world and that solid, well-guided research

could uncover motivations and explanations for community-specific similarities and variations in religious practices.

When studying religious beliefs, the focus is on configurations relating to the form of the belief and the content of the beliefs. Research that concentrates on the outward manifestations of beliefs, as well as on the linguistic and other symbolic forms of expression, is conducive to productive analysis in the social sciences. Raymond Firth maintains that beliefs not only are always culturally defined, but also have a core or nucleus that could be discernable in written and/or spoken creeds and dogmas.

Study of the concept of faith, according to Firth, involves a two-way process, with one path extending from the human to the supernatural and a second from the supernatural back to the individual. A reciprocal relationship is required for the continuation of a faith. In Catholicism, the believer offers prayers and sacrifices to a specific Saint, with the expectation of a return of some kind. The prayer, ritual, or sacrifice is provided with the expectation that an answer in some form will be forthcoming. If not, why perform the ritual? Why have faith that an answer will be forthcoming? There is an expectation of unification, a possibility of a connection between the giving and the expectation of a return.

What is also implicit in the act of exchange or sacrifice, according to Firth, is an “asymmetrical status relationship,” whereby the person making the offering is assigned an inferior position, while the recipient occupies a superior position. A hierarchy is in existence. A religious humanist researcher would question why a religious exchange is deemed necessary, contrasting and comparing various explanations for the participants. The focus is on what has occurred before the act, what is expected to happen during the act, and what the perceived outcome will be. The religious humanist believes that there is a discernable human logic underlying the values, beliefs, and behavior involved. A community ritual performance can be rationally interpreted as being performed because it allows for group social cohesiveness, providing a sense of belonging and reinforcement of specific moral values. The congregation provides unification of thoughts and actions for those with similar beliefs to coalesce and strengthen group unity, and it becomes a place for the individual to freely choose to belong and participate or to be coerced into choosing to belong and participate. The individual

may belong because of political and/or economic costs or benefits or for fear of punishment via gossip networks and the potential for exclusion from the community.

Rituals, performance, prayer, dance, and music are possible paths for communication with the supernatural. Public over private rituals demonstrate community acceptance of specific patterns of behavior, and as demonstrated by acceptable community standards serve the function of showing support for group unification. Roy Rappaport demonstrates in *Pigs for the Ancestors* how participation in a religious ritual dance among the Tsembaga Maring of New Guinea also affirms the dancers’ commitment to being part of the group in the event of war.

Secular humanism provides an alternative to metaphysical practices. The Council for Secular Humanism’s Web site states, “Secular humanists accept a worldview or philosophy called naturalism, in which the physical laws of the universe are not superseded by non-material or supernatural entities such as demons, gods, or other ‘spiritual’ beings outside the realm of the natural universe.” The website provides a list of guiding principles for participants. The first principle states, “A conviction of dogmas, ideologies and traditions, whether religious, political or social, must be weighed and tested by each individual and not simply accepted on faith.” This would tend to reinforce the interpretation that religion, like other social systems, should be open to empirical scrutiny, methodology, and, when deemed appropriate, capable of change.

HUMANISM, SECULAR

While the word *humanism* is recent, the idea of humanism is one of the oldest and most transnational worldviews in human history. Most worldviews are defined in terms of the distinctive beliefs they hold, but the principal feature of humanism is not so much its core articles of belief, but the method by which inquiry into the world is undertaken.

The American philosopher Paul Kurtz has provided the best understanding of humanism when he defined it in terms of its four constituent features. First and foremost, humanism is a method of inquiry; second, it presents a cosmic worldview; third, it offers a set of ethical recommendations for the individual's life stance; and, fourth, humanism expresses a number of social and political ideals. It is important to note the order in which these characteristics have been listed. Number 4 is the least important of them, not because social and political ideals are unimportant, but because the nature of those ideals has changed most over time and between continents. Numbers 2 and 3 are more important because the details of the worldview and the ethical recommendations have greater commonality between the various humanist civilizations of the world.

But the most important, because the most constant, is feature Number 1: Humanism is best understood as a method of inquiry. From the Carvakas and Ajivikas in India, from Kongfuzi and Wang Chong in China, from Thales and the Greek thinkers, through the Renaissance to the Enlightenment, to the 21st century, humanism is best understood as a method of inquiry. The *conclusions* of that inquiry—Numbers 2, 3, and 4 in Kurtz's definition—change between cultures and between centuries, but the *method* of inquiry has remained essentially the same.

Symptomatic of the uniqueness of humanism is that for most of its existence, it has functioned very well without the word. Humanism as a *concept* has its origins in ancient India, China, and Greece, each one arising independently, but the actual word was not coined until 1808, in Germany. To make things more complicated, *humanist* existed as a word long before *humanism*, originating in the Renaissance. But as humanism is defined principally by its method rather than by its conclusions, the lack of a word to act as a catchall for those conclusions is a trivial issue.

Another account of humanism, by the philosopher Mario Bunge, seems at first sight to come from a different perspective. In fact, Bunge's approach ends up saying things similar to Kurtz's shorter outline. Bunge speaks of humanism as involving concern for the lot of humanity. This concern he spells out in what he calls the seven theses of humanism, in this order: *cosmological thesis*: whatever exists is either natural or man-made; *anthropological thesis*: the common features of humanity are more significant than the differences; *axiological thesis*: there are some basic human values, like well-being, honesty, loyalty, solidarity, fairness, security, peace, and knowledge, and these are worth working, even fighting, for; *epistemological thesis*: it is possible to find out the truth about the world and ourselves with the help of experience, reason, imagination, and criticism; *moral thesis*: we should seek salvation in this life through work and thought; *social thesis*: liberty, equality, solidarity, and expertise in the management of the commonwealth; *political thesis*: while allowing freedom of and from religious worship, we should work toward the attainment or maintenance of a secular state.

Bunge is an advocate of what he calls "systemism," which postulates that every thing and every idea is a system or a component of another system. In this way, the first thesis covers the broadest territory and provides the foundation for the other theses. Looking at it another way, the theses run from the hard sciences through to the social sciences. Interestingly, in the first thesis, which addresses the individual human being, Bunge says what Kurtz also says, namely, the importance of the method of inquiry.

Humanism in the Ancient World

Humanism is the oldest and most transnational worldview on Earth, beginning quite independently in India, China, and Greece. The Carvakas were the materialist school of thought (*darshana*) in India, being traceable to the 6th century BCE. Carvaka philosophy regards the universe as interdependent and subject to perpetual evolution. Other important beliefs include the following: Sacred literature should be regarded as false; there is no deity, immortal soul, or afterlife; karma is inoperative and illusory; matter is the fundamental element; only direct perception, and not religious injunctions, can give us true knowledge. The aim in life is to get the maximum amount of pleasure from it. This had various interpretations,

from unalloyed hedonism, on one hand, to an altruistic service of others on the principle that this will maximize one's own happiness as well as that of others, on the other.

Other Indian movements of a broadly humanist orientation in India include the Ajivikas and the Sumaniya, about whom little is now known. The Ajivikas flourished between the 3rd and 6th centuries BCE, and their influence can be traced for more than 1,500 years. Like some early Jains and Buddhists, the Ajivikas went about naked, to indicate their contempt for worldly goods. In the main, they upheld a principle of nonaction, denying that merit accrued from virtuous activity or that demerit from wicked activity. Coupled with this was a thoroughgoing determinism and skepticism regarding karma and any sort of afterlife.

In contrast to India, the humanist strand in China became the principal strand of thought. This is largely, though by no means exclusively, due to the influence of Kongfuzi (479–551 BCE), who is known in West by his latinized name, Confucius. Confucius's genius involved transforming the naturalism and humanism latent in Chinese thinking into the strongest forces in Chinese thought, down to this day. He said that maintaining a distance from spiritual beings was a sign of wisdom; he expressed no opinion on the fate of souls and never encouraged prayer.

Confucius realigned the concept of *chun-tzu*, which had traditionally meant "son of the ruler," into "superior man," with the effect that nobility was no longer a matter of blood or birth, but of character. This was a very radical departure from customary Chinese thinking preceding him. Along with this, he radically transformed the notion of *jen* from meaning "kindliness" to the more general "man of the golden rule," or perfect *chun-tzu*. *Jen* was expressed in terms of *chung* and *shu*, or "conscientiousness" and "altruism."

In Greece, humanism can be traced back to the philosophers known as the pre-Socratics, that is, philosophers active before Socrates. The first of them was Thales (ca. 548–624 BCE), the man credited as being the "father of philosophy." Thales's claim to fame rests on being the first person to try to explain the world not in terms of myths, but by observation of the world as he actually saw it. Where Homer attributed the origin of all things to the God Oceanus, Thales taught that water was the prime element in all things.

The other thinkers who succeeded Thales took his thoughts in different directions, but their emphasis on studying the natural world and humanity's place in it remained the same. The humanist spirit was given its best voice by Socrates, who, during the trial for his life, declared that the unexamined life is not worth living.

The humanist tradition of Greek thought received a check in the philosophy of Plato and never fully recovered. Several Hellenistic movements, in particular Epicureanism and Stoicism, reflected important elements of humanist thought, but all had been effectively countered or crushed by Platonism and then by Christianity.

Renaissance Humanism

The collapse of the Roman Empire was followed by what can still justifiably be called the "Dark Ages." In these long centuries of faith and ignorance, the spirit of inquiry was almost lost in the West. It revived only with the Renaissance. In its broader sense, the Renaissance began with the life of Petrarch (1304–1374) and ended with the death at the stake of Giordano Bruno in 1600, with the most productive years of the Renaissance being the century before the sack of Rome in 1527.

Medieval thinking had been dominated by cultural pessimism: a weariness with this world and a suspicion, derived mainly from St. Augustine, that human affairs are inevitably tainted with corruption and selfishness. Renaissance thinking, by contrast, was positive and optimistic. While Renaissance humanism differed on many points, it was pretty unanimous in its condemnation of the monastic life, with all its implications of defeatism and withdrawing from one's civic duties. The very idea of Renaissance came from the idea that this age was the first to rediscover and appreciate fully the cultural grandeur of the ancient world. The thinkers of the Renaissance saw themselves as the scourge of medieval dogma and pioneers of a new cultural and intellectual orientation centering on the majesty of the ancient world. The new style of thinking was stimulated by the rediscovery of ancient thinkers, in particular Lucretius, Cicero, and Plato. The Renaissance humanists were optimistic about the power of culture to effect positive social change. Only after the sack of Rome in 1527 did this optimism decline and a return to contemplation and an escape from the world once more became a discernable trend in Renaissance thought.

Very few Renaissance thinkers were atheists: Almost all were theists, and the majority of them remained Christians, though of heterodox sympathies. But the understanding of God changed. God was something that could be understood by our learning and study. Indeed, learning and study was a deeply pious activity, in that learning about nature meant, ipso facto, learning about God. The Renaissance was a period of significant historical and scriptural research. For instance, Lorenzo Valla (1405–1457) was responsible for exposing the fraud known as the “Donation of Constantine,” upon which the papal claims to own its large territories in Italy was based. Valla also wrote *Dialogue on Freewill*, a frankly skeptical work, and a very sympathetic account of Epicurus. Valla was influential in teaching people the need to read scriptures with a skeptical frame of mind. This religious scholarship of Renaissance scholars was usually undertaken with a mind to reform religion and purge it of its recent and harmful additions. This drive led directly to developing some of the first ideas since the ancient world of religious toleration. This trend came to an end only when the religious reformer Savonarola was burned at the stake in 1498.

Contemporary Secular Humanism

The humanism of the ancient world and the Renaissance were both stifled by religious reaction. The dramatic growth in humanism in the modern world is due to the declining power of religion to coerce belief and also the growing power of science to give strong support to Bunge’s cosmological thesis. The revolution in thinking brought on by the Copernican revolution has been profound. No longer can humans credibly consider themselves the center of the universe. Concurrent discoveries of other civilizations by European explorers also showed that people could live quite happily without Christianity. The Enlightenment in Europe (roughly, the years between the 1680s to the 1780s) was characterized in part by the taking to heart of this realization.

If the Copernican revolution greatly demoted humanity’s place in the cosmos, the onset of the Darwinian revolution in the 19th and 20th centuries meant an end to the conceit of seeing humanity as the pinnacle of creation, below only God, in whose image we are made. The current developments in genetics and brain science are certain to challenge those essentialist

theories of humanity, which still linger on. So the story of contemporary humanism is the story of the progressive appreciation of humanity’s part in an interdependent system. It is with this insight in mind that Bunge’s seven theses of humanism have their value.

Contemporary secular humanism has been able to organize in a self-conscious way that was not possible for its ancient or Renaissance predecessors. There are now humanist organizations in most countries of the world. This change has been made possible by the coming together of the concept of humanism from the ancient world, the adjective *humanist* from the Renaissance, and the noun *humanism* from the 19th century.

Returning to Paul Kurtz’s outline of humanism, we can trace the changes in two of the points and the continuities in the other two. Item 2, the cosmic worldview, has become more modest and less geocentric, as required by developments in astronomy and cosmology. Item 4, the political ideals, has become inclusive of more groups than earlier humanisms would have endorsed. Toleration of slavery in ancient Greece and the widespread misogyny found in Confucianism and Greek thinking no longer play a part in secular humanist thinking.

In contrast to these changes, Item 3, the ethical ideals, have remained fundamentally the same. The values identified by Solon, Pericles, Confucius, the Carvakas, and the Epicureans still resonate today. Enjoying the moment, resisting the transcendental temptation, love of nature, impatience with display, imperviousness to materialism, civic values, and family responsibility all were recommended by the ancient humanists, and all find enthusiastic support among their contemporary successors.

But it is the first item of Kurtz’s outline that has remained the most constant. The endorsements of skeptical, open-minded inquiry given by Socrates, Wang Chong, and the Ajivika thinker Upaka find direct parallels in the work of Bertrand Russell, Albert Einstein, and all the other humanist philosophers and scientists who have shaped the modern world. Humanism is first and foremost a method of inquiry, and it is the conclusions of that inquiry that furnish us with our ideas and beliefs. Humanists have always rejected static formulas of thought, bowing to arguments from authority or accepting command moralities. In contrast to systems that are founded on acceptance of bodies of thought, humanism assumes

that as knowledge comes from humans, it is bound to include some element of error, and it therefore will be in need of revision as our learning grows. In this way, contemporary humanism can reject the anthropocentric conceit of the Renaissance humanists, the hedonism of the Carvakas, the humorlessness of the Stoics, and still honor their role in the long stream of humanist thought. And as our scientific and philosophic knowledge grows, doubtless some important features of 21st-century humanism will be replaced. But the primacy of humanism as a method of inquiry will remain.

SECULARIZATION

Secularization is the process related to modernization and industrialization through which religious institutions, rituals, and beliefs lose their importance in societies. Several theories of secularization are influenced by evolutionist anthropology, which assumed that human societies

evolve through different stages, becoming increasingly complex and sophisticated in their social organization. Theorists of secularization conceived the advent of modernity as the progressive marginalization of premodern forms of knowledge, including religion, by science.

Building on Max Weber's "disenchantment of the world," they argued that the development of rational forms of social organization and rational modes of thought would liberate humankind from the irrationalities of myth and religion. Some theorists also thought that the contact among different religious groups in contemporary cosmopolitan societies diminished each individual's sense of belonging to the best religion.

Governments and other institutions can also play an important part in the process of secularization by reducing social inequalities among people, thus handling peoples' problems in place of religious groups.

In a secular society, all the superhuman and supernatural forces that populated the universe of pre-industrial cultures, and were responsible for the phenomena of the natural and social worlds, are replaced by modern scientific interpretations. As explained by Weber, only the laws and regularities discovered by the scientific method are validated as explanations of phenomena. Secularization is not the result of the increased capacity of humans to think rationally, but the emergence of a form of knowledge whose claims are demonstrably true and applicable. The process of secularization first became observable during the 17th century in Europe and gained prominence with Protestantism. Since then, it has spread through colonialism to other non-European countries.

Secularization is an undeniable tendency of contemporary societies. Yet, its legacy is an ambiguous one. On the one hand, traditional religious rituals are losing their centrality in social life and are becoming almost leisure-time activities. States such as France are equipping themselves with laws to protect their secularism, prohibiting the exhibition of religious symbols in public spaces such as schools. On the other hand, the complexity of modern societies is proving frustrating for many people and the responses of central secular governments to peoples' problems have failed to construct inclusive communities. In European

nations such as Italy, the Catholic Church can still play an influential role in both the social and political life.

The chaos of the contemporary world has also prompted people to look for reassuring responses and for a sense of community in nontraditional religious groups such as cults and sects. In the United States, Canada, and Western European states, religious revivals have taken place thanks to the ability of cults to recruit their members on a wide social spectrum. One of the most challenging debates of the coming years will be whether sects will rekindle religious sentiment in our societies or whether the process of secularization will prevail over sectarianism.

— Luca Prono

HUMANKIND, PSYCHIC UNITY OF

Anthropology, the study of human beings in their bedazzling variety, eternally provokes questions about what human beings share, about their similarity, unity, or identity. The doctrine of the psychic unity of humankind is an answer to that question. Humans, it claims, are characterized by something more than merely biological unity. Equally, they are characterized by something less than spiritual unity, at least insofar as we fail to semantically disentangle “spirit” from a parochial Christian ontology and theology.

The psychic unity of humankind (or mankind) enters the anthropological lexicon in the work of Adolf Bastian (1826–1905). The idea itself, however, is too large to belong to any single person. An intimation that there is a “humanity” and that it is “one,” regardless of differences of caste, age, sex, or nation, is ethnographically rare but not unique. The historian of ideas, Eric Voegelin (1901–1985), suggests that the roots of this notion go back to the era of the ancient Mesopotamian city-states and the conviction they subsequently furnished that, standing as we do beneath the same sun, we are all equal.

Other sources for the idea have been essayed by the anthropologist Klaus-Peter Koepping. Particularly significant was the Stoics’ challenge to the distinction between Greek and barbarian; Cicero’s

(106 BC–43 BC) coining of the term *humanitas*; the Renaissance ideal of the virtuous human as a cosmopolitan “universal human”; and the Enlightenment’s championing of the “brotherhood of mankind.” Nor should we neglect the transformation of the Jewish image of the one God into a universal God for all peoples in Pauline Christianity, along with the radicalization of this idea in numerous peasant revolts and ecclesiastical reform movements, right up to the utopian socialism of the early 19th century and beyond.

Popular within anthropology from its mid-19th- to early 20th-century beginnings, the psychic unity of humankind was a scientific postulate that fed from all these general influences. Today the phrase mostly surfaces in anthropological writings as a throwaway citation. Occasionally, as Melville Herskovits already noted in 1959, it is referred to approvingly but usually on the understanding that it no longer has any substantive theoretical role to play.

Nonetheless, the idea arguably remains at the very heart of the anthropological enterprise, though less as a still center of intellectual gravity than as a magnet possessing both attractive and repulsive poles. This curious centrality can be conveniently discussed by distinguishing between the *synthetic*, the *programmatic*, and the *normative* dimensions of the idea.

Inductive Synthesis

An indefatigable traveler and collector of ethnographic data, Bastian was also an ambitious conceptual synthesizer. He recognized that all ethnic groups generated their own collective representations; that across this variety of characteristic representations it was possible to discern certain elementary ideas; and that the presence of these elementary ideas counted as compelling evidence for the psychic unity of all peoples.

The doctrine was soon put to use in a number of early anthropological disputes. Can we account for cultural similarities between different peoples by recourse to the diffusion of ideas from a common source or in the course of historical contacts? The doctrine suggested we could not. In many cases, common origins are too ancient and/or there is no credible evidence of contact; so it must rather be the case that the human mind is such as to independently generate similar ideas when faced by similar problems and circumstances. Moreover, contact without psychic unity is insufficient on its own to explain the diffusion of ideas.

Is humanity one (the monogenetic claim) or several (the polygenetic claim)? The doctrine of psychic unity suggested that humankind was one race. Is history a story of degeneration from noble beginnings with no possibility for “primitives” to become “civilized”? Coupled to an evolutionary story that took note of cultural elements surviving from earlier phases even in the most civilized societies, the doctrine of psychic unity suggested rather that primitive peoples could make advances.

Popularized by Edward Burnett Tylor (1832–1917), this latter argument firmly linked the psychic unity of humankind to progressivist and evolutionary theories in anthropology. World War I dealt harshly with all varieties of progressivist optimism. The hugely influential cultural particularism of Franz Boas (1858–1942) dealt equally harshly with evolutionism in anthropology. Boas himself endorsed the idea of psychic unity, arguing persuasively that all peoples had essentially equal intellectual capacities and moral faculties. Nonetheless, with everything distinctively human elucidated by reference to discrete cultures, psychic unity became an explanatory empty set.

The fact that an emphasis on cultural particulars has made many anthropologists suspicious of human universals provides one reason for the eclipse of Bastian’s doctrine. A further reason is that when 20th-century anthropologists did swim against the Boasian tide to seek generalizations applicable to all cultures, they more commonly swam “downstream” in search of social, economic, ecological, and biological regularities than “upstream” to the psyche.

Research Program

Countercurrents, to be sure, have not been absent. Among his elementary ideas, Bastian counted space, time, numbers, and the cross. Subsequent investigations, whether conducted to establish evidence for psychic unity or for cultural diffusion, have by now confirmed a large inventory of images and symbols occurring in the most far-flung cultures. The snake or the serpent, often eating its own tail (the uroboros) or in the beak of an eagle; the dragon; the swastika; the tree of life; the omphalos (navel of the world); the association of the left hand with disorder or cunning and the right hand with what is “right”: These and other primary images or symbols are so widespread as to make fair bid to be called universal.

An exhaustive itemization and analysis of these and countless images of a more idiosyncratic nature was undertaken by Gilbert Durand. Interest in their archetypal significance has been strongest among ethnographically informed Jungian thinkers such as Eric Neumann (1905–1960) and Mircea Eliade (1907–1986). The Freudian approach is well represented by the pioneering psychoanalytic anthropologists Géza Róheim (1891–1953) and George Devereux (1908–1985), who used parallels and divergences between field data and material emerging from psychoanalytic case studies to illuminate each other. The cognitive anthropologist James Silverberg stressed the fact that rapport between observer and observed in the field would be impossible in the absence of psychic unity, and suggested that the empirical investigation of logical and inference-making universals was best pitched at the level of discourse. Lévi-Strauss, most ambitious of all, sought to properly locate socio-cultural phenomena by identifying isomorphic processes and structures at work in physical, biological, linguistic, and psychological phenomena.

These are some of the signal resources currently available for thinking about the substantial content of the human psyche and its dynamic entwinement in varied sociocultural formations. They are not, however, resources that the discipline in general has taken up. It might seem that for anthropology as a whole, the psychic unity idea has been reduced to little more than an uninformative consensus that humanity is all one. But this is a false impression.

Virtually any line traced through the intellectual history of anthropology reveals itself as a tacit tacking back and forth across the wind of Bastian’s fundamental concept. This is true whether the issue is cultural relativism, gender, number, the body, color discrimination, culture and personality, human evolution, the psyche itself, or native responses to Captain Cook.

Lewis Henry Morgan (1818–1881), for example, held to a monogenetic view, arguing that the brain of the “savage” and the brain of the “civilized person” were the “same brain.” Judged from the perspective of polygenesis, Morgan’s work supported the doctrine of psychic unity. And yet Morgan supposed in a Lamarckian vein that with the progress of social and technological evolution, morality and intelligence developed further, were subject to inheritance, and were stored in an increasingly larger brain.

For Bronislaw Malinovsky (1884–1942) this evolutionary schema shortchanged primitive peoples. They

needed to be understood in their own terms and in any case had desires comparable to the rest of us. What were those common desires? Well, they did not have the character supposed by many in bourgeois Europe. By demonstrating that the significance of wealth among the Trobrianders derived from the social importance attached to *giving*, Malinovsky undermined the utilitarian view that every person everywhere was a self-maximizing *H. economicus*.

And yet according to Marcel Mauss (1872–1950), Malinovsky had not gone far enough. He failed to really part company with utilitarianism, for he thought it possible to assess the individual motivations of Trobrianders by putting their separate exchanges on a continuum from pure gift giving to bargaining for gain. It therefore fell to Mauss to argue that the very contrast between disinterested giving and self-maximization was out of place. Giving and receiving in clan societies was religious, economic, aesthetic, legal, and so on, all at once. There was no separate economy, and no separable economically motivated actor, to be found in such societies.

The key question here is whether such debates are in any way cumulative. To the extent that they are, their virtue does *not* lie simply in taking this or that widespread assumption about what is common to the human mind and using ethnographic data to expose the assumption as a false universal. It lies rather in forcing the universal to become more concrete, that is, more ethnographically informed and therefore more genuinely universal. The “psychic unity of humankind” in this sense is not merely some outdated 19th-century doctrine, but an unstated research program, the name of a sprawling conceptual terrain that anthropologists are collectively mapping out.

Normative Horizons

Expressing the foregoing somewhat enigmatically, we might say that even if anthropology has forgotten the psychic unity of humankind, the psychic unity of humankind has not forgotten anthropology. This is most apparent when we turn to the normative dimension of the concept.

To speak of the psychic unity of humankind as having a programmatic value for anthropology is to indicate that it is more than a curiosity-driven search for human universals. Ineluctably, the idea has ethical significance. For attempting to inform humans about what they are and what they have in common is not

a neutral act. By contributing its share, anthropology becomes part of the world-historical process by which human unity comes to exist in a new sense in virtue of being *known* to exist.

Without a doubt, anthropology’s flagship achievement in this area is the blow dealt to racism. Handed an ethnographic mirror in which to see itself anew, humanity, and most particularly European humanity, had a better chance to recognize why racism was blinkered and wrong.

What is equally interesting is that the psychic unity of humankind also has a reverse ethical significance. It is a telling fact that on first acquaintance the phrase may sound *dystopian*, a perfect doctrine for a Kentucky Fried world striving all too successfully to become one unified place.

The psychic unity of humans, in fact, is a doctrine that straddles what may be *the* antinomy of anthropological thought in the ethicopolitical realm: the imperative, on the one side, to stand up for the rights of all people to a fair share of the possibilities the modern world makes available, and the imperative, on the other side, to stand opposed to the hydrochloric acid of the Western cultural stomach and its insatiable will to digest and assimilate all otherness into itself.

On the surface it appears that even if anthropology has come up with no way of reconciling the imperative of global equality with the imperative of global diversity, at least it is an intellectual arena in which the competing claims of each may be faced and argued over. But in fact more might be asserted than this. For considered in a historical sense, what else is the gifting to the world of a more culturally differentiated universal, a more concrete and accurate sense of humanity’s psychic unity, than a labor on behalf of a humanity that must draw together without squandering its priceless diversity? Anthropology at its best, and that includes a figure like Bastian, has always seen itself as helping to bring about a “world culture” of a different order than the one presently doing the rounds.

UNITY OF HUMANKIND

First theorized by ethnologist Adolf Bastian (1826–1905), the psychic unity of humankind postulates that there are certain elementary ideas and concepts that are common to all people. Bastian proposed that cultural features, folklore, myths, and values of various ethnic groups originate within each group according to laws of cultural evolution and are essentially the same. The only differences that are detectable are formal and are due to the geographic environment. Bastian's unity of humankind theory has influenced a number of prominent anthropologists, including Bronislaw Malinowski and Franz Boas, as well as Carl Gustav Jung's psychoanalytic theory of the collective unconscious. The unity of humankind concept has become anthropology's oldest and most problematic question.

Studying shamanism, Bastian described it as a configuration that covered much of the globe. The

shamanic phenomenon was considered by Bastian as a widespread elementary idea (*Elementargedanken*), whose individual embodiments (*Volkergedanken*) appeared in many different cultures under a variety of names. Shamanism, with its strong links to a hunting way of life, arose independently in places as diverse as the Arctic tundra and tropical forests. The distribution of shamanism on all six inhabited continents, like the occurrence of the nuclear family, the mother-son incest taboo, and the notion of property, is a function of the evolution of the human brain and not the result of historical phenomena, such as migrations, or of biological variations.

The belief in the unity of humankind engineered by cultural evolution led 19th-century anthropologists such as E. B. Taylor (1832–1917) and Lewis H. Morgan (1818–81) to detect several stages in the cultural development of humanity. As Morgan put it in *Ancient Society* (1877), “Since mankind were one in origin, their career has been essentially one, running in different but uniform channels upon all continents, and very similarly in all the tribes and nations of mankind down to the same status of advancement.” Yet the theory of the stages was challenged at the turn of the 20th century, when anthropologists, such as Boas, Margaret Mead, and Ruth Benedict, argued that the discipline should move away from generalizations to focus instead on fieldwork on single cultures.

The unity of humankind theory has proved a theoretical challenge to the other important tenet of cultural anthropology: the notion of human cultural difference. The faith in a single human nature is difficult to reconcile with the defense of cultural relativism. Contemporary American anthropologists such as Leslie A. White, Julian H. Steward, Marshall D. Sahlins, and Elman R. Service have tried to address this apparent contradiction. They have claimed that although there is not a single process of evolution valid for all peoples, it is true that humankind generally evolves and progresses. Specific peoples supply innovations that make all humankind more dominant over the environment and more complex both socially and culturally.

— Luca Prono

HUMANS AND DINOSAURS

Dinosaurs were a diverse and successful group of animals whose remains have fascinated us and inspired myths that persist into modern times. Although the last dinosaur died 63 million years before the first human, some stories infer contemporaneous existence or defy the fact of their demise. Behind these narrative relationships may lie an innate interest in what ended the reign of such successful creatures, as realization grows that humans are not exempt from similar factors causing their own fate.

Dinosaurs beheld the world long before humans. They evolved 230 million years ago on the single continent that was then the land surface of the earth. As the pieces of Pangaea separated and slowly drifted apart, their descendants were carried across the surface of the globe to become a hugely diverse and successful force of terrestrial ecology. They left traces of their existence on every continent, fossilized as tracks or bones preserved by geological accident. After a 165-million-year reign on earth, they suffered an abrupt demise, leaving their feathered descendants to fly over a world that was now safe for mammals. It would be another 58 million years until the first hominids appeared in present-day Africa, and a further 6 million years before our genus *Homo* could gaze upon the fossilized traces, and wonder . . .

Dinosaurs have long held deep fascination for humans. Their large and strange bones, continuously being exposed naturally by erosion, were encountered with amazement by ancient peoples. With no concept that animals once alive may have become extinct, speculation on the obviously dangerous creature that must visit from somewhere over the horizon inspired imagination and fear, and thus were born mythological creatures such as dragons, griffins, and winged serpents. Noting the similarity of sharp teeth and long tails of some dinosaur skeletons to familiar animals, depictions of dragons carried heads like a lion and bodies of snakelike form. Commonly, these reconstructions had wings, a not-too-inaccurate reconstruction of some dinosaurs that share close ancestry with birds. The additional inference of flight explained how the mythological creature could travel between its unseen lair and the local environment where its mortal remains lay.

These mythological explanations were later supplanted by formal religious beliefs, as in the Genesis

account of the creation. Rational thought on how organisms can develop, change, and end would precipitate only in the last three centuries of human evolution. Yet stories and myth about humans and dinosaurs coexisting persist in some countries.

In central Africa and South America, legends tell of “Mokele-mbembe,” alluding to a still-living sauropod dinosaur, while in Europe, local myths infer other creatures left over from the Mesozoic age of dinosaurs are still rearing their heads. The purveyors of these stories do not seem to consider that animals cannot live forever as individuals; a herd of dinosaurs large enough to form a sustainable breeding population this last 65 million years would be hard to miss even in the jungles of Congo, never mind around the tourist-tramped shores of Scottish Loch Ness.

In North America, supposedly human footprint traces are claimed to occur with those of dinosaurs at a small number of dinosaur track sites. Studies have revealed that the claimed human prints are in fact misidentified dinosaur tracks, natural erosions, or carvings by hoaxers and others with vested interests in myth. In some locales, there have arisen small industries to perpetuate and trade on such stories, sustaining fundraising from tourism and religious cultures.

In thousands of excavations around the world, on every continent, while recovering fossils and traces of tens of thousands of species of flora and fauna, no dinosaur and human remains have ever been found together to suggest any contemporaneous existence. The gap in time between the last dinosaurs to the earliest human being is approximately 30 times that of the entire existence of humans on the planet: The earliest *Homo* remains date to about 2 million years ago, and you have to travel 30 times that number further back in time to the last of the dinosaurs. This gap of 63 million years dwarfs the short history of human evolution and is a vast ocean across which no contemporaneous existence can cross. Even human myth must at some stage be diluted by the fact that the dinosaurs are gone forever.

After 165 million years of terrestrial domination, the dinosaurs became extinct at the end of the Cretaceous period during the most notorious of five mass extinction events in life’s history. They were a major group but only one of a large percentage of the world’s flora and fauna that became extinct in a profound turnover of the earth’s biota at that time. And

what unfortunate series of events conspired to overcome the hitherto successful dinosaurs? Arguments continue to rage. There was massive volcanism and widespread marine regression toward the end of the Cretaceous, but the rate and scale of change these would have imposed on climate and environment is unclear. The evidence for the publicly popular theory of meteorite impact is well supported, with the necessary-size crater and over 110 sites documented with evidence of impact fallout such as Iridium and shocked quartz, yet the size and tempo of stresses this would induce upon life are hard to model.

Each hypothesis has its own complex mechanisms and interactions to explain the results seen in the fossil record. The anomalies in the patterns of surviving taxa are difficult to explain by a single theory, such as why birds survived while pterosaurs did not; so arguments as to the type and tempo of causes and mechanisms continue. There may be growing consensus that the patterns of extinction and survival indicate a more complex scenario than a single event might suggest, such as a combination of events causing a stressful rate of environmental change, with the meteorite impact being the coup de grace upon an already worsening fitness landscape. Although an exact and complete answer to the question of dinosaur extinction is yet to be ascertained, the discovery of the complexity of mechanisms involved has led to growing realizations about extinction processes and what they may look like in the modern world.

Underlying our continued fascination with dinosaurs as excitingly different creatures is a more fundamental and serious need. For humans may be naturally curious, as befits our mammalian development, but we also have a primal drive for answers to potentially fatal questions. What dangers can we expect to find in our own fitness landscapes, and what will they look like at an early stage? Are we adapting to evolutionary pressures successfully, and if not, what will signs of our own demise look like?

Dinosaurs, as robust fossils of great diversity over a long period of time, provide a useful record of life history with which to compare our own progress. There is increased awareness that humans too have to navigate the same evolutionary pressures that descended upon the dinosaurs and caused the demise of their once mighty branch of life. In this way, dinosaurs provide us with more than myth and movies, and are also illuminating the potential paths

of development that humans must travel to become exempt from the same evolutionary fate.

VON HUMBOLDT, FRIEDRICH WILHELM HEINRICH ALEXANDER (1769–1859)

Alexander von Humboldt felicitously combined acute observation and scientific method with indefatigable energy levels and enormous curiosity. The Age of Humboldt, as some called it, was an age in which scientific method first conquered speculation and the world became a single world where the same processes, physical and human, could be thought to apply everywhere. Born September 14, 1769 in Berlin, the son of a Prussian officer and a Huguenot mother (whose family left France in 1685), Humboldt studied at various universities (Frankfurt, Berlin, and Göttingen), where he became interested in geology and botany. In 1790, he enrolled in the Mining School in Freiberg and then took a job in the Prussian government's department of mines (1792). In 1796, his mother died and he came into an inheritance worth about £17,000, which provided an annual income of about £700—vastly higher than his income as a government functionary of £80 per year. This inheritance helped subvention his travels and publications until it was finally exhausted around 1827. Humboldt lived in Paris during many of his most productive years where

he had a close friendship with physicist François Arago, but he also often resided in Berlin, where he died on May 6, 1859.

Humboldt traveled widely in Europe as well as the Americas (Central and South: 1799–1804) and Central Asia (1827). He was able to both write prodigiously about what he saw and to formulate fruitful generalizations that became the starting points for later disciplines, including physical geography, landscape ecology, climatology, and even vulcanology. He was the first to establish the difference between sedimentary and igneous rocks and to suggest that volcanoes were linked to fault lines. He devoted hours taking measurements, which he assiduously turned into statistics that he related to botanical and geological observations. Humboldt had a genius for graphical representation and was the first to introduce the depiction of isoclines and similar graphics using his many individual data points for magnetic readings, temperature, or barometric pressure.

Humboldt's observations tended to be acute: The Peru Current was originally named the Humboldt Current since he was the first to record its consistently colder temperatures. His observations that the limestone in Jura (Italy) obviously represented a distinct geological period led him to coin the term “jurassic,” and his claim that South American savannas had a climatic origin is still a matter of theoretical interest. While authorities recognize some examples of anthropogenic influence, they tend to view Humboldt as correct in many other cases. His careful observations of traditional American peoples and civilizations even led him to hypothesize and provide substantial evidence for an origin across the Bering Strait from Siberia (1810) in contrast to the many speculative theories that then prevailed. Nevertheless, while he strongly promoted the career of Louis Agassiz, he still found it difficult to believe Agassiz's theories of earlier ice ages, and his spotty education prevented him from fully understanding the mathematics behind Gauss's model of earth's magnetism.

Humboldt was perhaps most unique in his energetic devotion to a scientific methodology in which hypotheses were assiduously exposed to all supporting and countervailing evidence and plausible conclusions reached only after evaluation of both. His enormous influence in his time was equally due to his prolific travel, acute observation, insightful generalization, and his ability to network with other scholars and governments. Humboldt was generous with his

time and money, and though he died quite poor, his personal correspondence always involved a vast international network of scholars.

HUME, DAVID (1711–1776)

Contrary to the traditional conception of human beings as essentially purely rational, David Hume, Scottish philosopher, historian, and essayist, argued that both reason and passion are essential parts of human nature. On the basis of his view of human nature, he hoped to radically reconstruct the moral discourse of his time. This led to his condemnation as an atheist and skeptic. Charles Darwin counted Hume as a central influence, as did Thomas Henry Huxley.

Life and Works

David Hume was born in 1711 near Edinburgh. He studied science and read widely in history, literature, and philosophy. In his mid-20s, he wrote his first, greatest, and most influential philosophical work, his three-volume *Treatise of Human Nature*, a difficult and provocative book. To Hume's disappointment, the book failed to gain attention. Therefore, in 1741

and 1742, he published his *Essays, Moral and Political* to get his ideas across to a general public. With their popular style, the essays were more successful than the *Treatise*. But being condemned as an atheist and skeptic—he despised the “monkish virtues” of humility and self-denial—Hume never obtained an academic post. Popular revisions of his *Treatise* (*Enquiry Concerning Human Understanding* and *Enquiry Concerning The Principles of Morals*) were published in 1748 and 1751. In 1751, Hume also published his *Political Discourses*, which drew immediate praise. But his most successful book was his six-volume *History of England*, published from 1754 to 1762. This work made Hume quite wealthy. After having held diverse professional positions and having spent several years of his life abroad (in France, Austria, and Italy), Hume could spend his last years in Edinburgh quietly and comfortably, dining and conversing with friends in Edinburgh’s intellectual circles.

Empiricism

Following the newly developed natural sciences of the 17th century, Hume wanted to establish a science of human nature that would be free of false and misleading metaphysics or superstition. His aim was to find the explanatory principles that produce order in diverse phenomena of human nature. In general, he thought that a study of history and an examination of all known societies suggested that these principles of human nature are as universal and immutable as those governing the rest of the natural world.

Impressions, Ideas, and Personal Identity

Hume criticized the traditional conception of human nature, which identified the capacity for reasoning as the true human nature. In his account, the passions are likewise potentially positive and beneficent parts of human nature. The materials of thinking (perceptions) are divided into ideas (thoughts) and impressions (sensations, such as colors and sounds, and passions, such as being happy or afraid). He argued that all ideas are ultimately derived from impressions, a thesis usually called the *copy principle*. But ideas are also regularly connected. It is the faculty of imagination that combines simpler ideas into new structures. The imagination flows from one idea to another via three principles of association: resemblance, contiguity in time or place, and cause and effect.

Source: Courtesy, Wikipedia.

On this account, Hume was skeptical about personal identity. He claimed that we have no experience of a simple, individual impression that we can call “the self.” He diagnosed that we naturally (mis)take a highly constant and coherent series of momentary perceptions for a continuous mental substance (the self). Because of the associative principles, the resemblance or causal connection within the chain of our perceptions gives rise to an idea of oneself, and memory extends this idea past our immediate perceptions.

Passions, Motivation, and Freedom of the Will

Passions like pride and humility, love and hatred play a prominent role in human life and for this reason attracted Hume’s attention. Because Hume takes human nature as universal and unchanging, both over time and across cultural divides, he takes, for example, the mechanism behind the causes of the passions of pride as natural, that is, independent of convention. Pride is evoked by some intrinsically pleasurable factor when seen as relating to oneself. The particular things that cause pride, however, may change over time or culture. In contrast to pride and humility, which are self-directed states, love and

hatred are caused by reflecting on someone else. Love naturally leads to benevolence, whereas hatred is constantly conjoined with anger. Some passions are influenced by the opinions and sentiments of others. The capacity to simulate what others are experiencing when we see or think of them is sympathy. Hume also argued that human actions must be prompted by passion and never can be motivated by reason alone. Thus, Hume concluded that “reason is, and ought only to be, the slave of the passions.”

On the issue of freedom of the will, Hume reconciled necessity with liberty. Although human behavior is just as predictable and explicable as any other natural phenomenon, necessity does not eliminate moral choice, because we rely on necessity to link a person’s actions with his motives and thus pass moral judgment on the person’s actions. Hume regarded an action as free when it systematically emerged from settled character traits.

Morality and the Seduction to Virtue

In his moral theory, Hume tried to reduce the phenomena of moral judgment, virtues, and vices to as few principles as possible. The starting point is an observation of the kinds of acts that elicit moral approval and the character traits constantly conjoined with them (i.e., virtues). This investigation reveals in Hume’s account four primary sources of moral virtue: (1) qualities useful to others (beneficence, justice, and veracity); (2) qualities useful to oneself (prudence, perseverance, and patience); (3) qualities immediately agreeable to those who encounter or consider them (wit, eloquence, and cleanliness); and (4) qualities immediately agreeable to oneself (good humor, self-esteem, and pride).

Making a moral judgment, people approve or disapprove of certain qualities. Moral distinctions do not derive solely from reason but are passions that come from a general and stable viewpoint. In *Enquiry Concerning the Principles of Morals*, Hume names the central moral passion the “extended or extensive sentiment of humanity,” which is a disinterested desire for the benefit of any person purely on account of shared humanity. Hume was very optimistic about human nature and morality: The sentiment of humanity could be found in everyone. No transcendental moral law has to be imposed upon people, because moral requirements are requirements of

human nature itself. Hume’s work on morality was motivated by the conviction that outlining and communicating this truth to people would seduce them to be virtuous.

HUNTINGTON, SAMUEL P. (1927–)

Samuel P. Huntington is one of the most talked-about and controversial political scientists in the world today. Huntington asks the question, “Who are we?” of Americans, contrasting many different cultures to our own. Instead of a unipolar world in which America is the lone superpower, he sees humanity instead more accurately organized into nine major cultures: Hindu, Orthodox (Russian, Slavic), Latin American, Western, Islam, Confucian, African, Buddhist, and Japanese. He also investigates in his writings how these cultures will compete for preeminence in the world in the 21st century.

Born in New York City in 1927, Huntington has worked in government at the highest level. He earned his bachelor’s degree at Yale University in 1946, his master’s degree at the University of Chicago in 1948, and his PhD at Harvard University in 1951. He founded and coedited the magazine *Foreign Policy* (1970–1977) and was a member of the National Security Council from 1977 to 1978, where he served as Coordinator of Security Planning in the Carter Administration. Huntington is currently professor of political science and director of the John M. Olin Institute for Strategic Studies at Harvard University.

One of Huntington’s main theses is that the West (comprising the U.S., Canada, and Western Europe) is facing the decline of its power relative to other

cultures such as Islamic and Confucian (or Chinese) culture. The end of the Cold War has seen the attempted imposition of Western values on the rest of the world. This effort has been rejected by most of the Muslim world and others, including Cuba, China, and parts of Latin America. “Winning” the Cold War, however, does not translate to the creation of a democratic world in which Western values are substituted for all others.

Huntington sees the main threats to Western culture as coming from Islam and China. Economically, China continues to grow at a higher rate than the West. This is balanced by the West’s continued technological superiority. Huntington sees this state of affairs as temporary, however. Over the next decade, China will achieve near military parity with the United States. In Asia, China is the main trading partner of most of the countries in the region. The smaller nations of South Asia may look to China for leadership in economic and political affairs, while China simultaneously makes an effort to increase its influence among the region.

Concerning the Islamic world, according to Huntington, the West is at a disadvantage due to a simultaneous slow (nearly zero) birth rate in the West and an exploding birth rate for Muslims. Anti-Americanism in these countries continues to be politically supported by large segments of Muslims. Arms sales from China to Syria, Iran, Libya, and other Muslim nations are warning signs that should be heeded by Western political leaders. However, since Islam has no “core country” as the West does (the U.S.), this inhibits the culture’s dominance and its spread to non-Islamic countries.

Huntington’s most recent book, *Who Are We? The Challenges to America’s National Identity*, focuses on immigration into the United States, particularly Mexican and Hispanic immigration over the last 20 years. Huntington fears the loss of a unique American identity. He forecasts the wave of Hispanic/Mexican immigration to be an acute source of future cultural and political conflict. Huntington envisions a situation similar to Canada, in which French-speaking citizens of one or two provinces desire political autonomy or outright secession. He writes of the “American Creed,” which values the English language, legal systems based on British law, our own traditions of democracy and individual liberty, and equality for women. Historically, immigrants have gradually assimilated into American society, combining these

values with their own. As Huntington sees it, the last two decades of Mexican immigration have not witnessed the same type of “melting pot”—the newcomers instead simply move their cultures with them and have no intention of learning English or being assimilated into American culture. Another cause for alarm, according to Huntington, is that unlike other immigrations in U.S. history, Mexicans are closer in proximity to their home country, they can hold dual citizenship, they are much more numerous than other immigrants, and they possess a possible desire to redraw the map of the southwestern United States to reclaim lost territory from the mid-1800s.

At the same time, Huntington sees an internal enemy, the liberal elites who favor a “world community” model of nations. These are the influential politicians and policymakers who defer to the United Nations, international agreements such as the Kyoto Protocol on the environment, and the World Court. American sovereignty is to these people a thing of the past, having little if any relevance in the age of transnational corporations and worldwide communications technology. Huntington believes that American values are superior to all others and to act in concert with other nations can compromise our national interests.

Huntington’s fault lines are sometimes inaccurate. Mexican immigrants, especially second- and third-generation Hispanics, *do* speak English, and the third generation will speak *only* English. Those granted U.S. citizenship are proud to be Americans. Instead of a unified Islamic civilization, the United Nations’ response after Saddam Hussein invaded Kuwait shows how states act according to national interest, not along supposed culturally divided lines. A military coalition of the West, other Arab states, and Japan fought against the Arab Iraqis to preserve the political status quo in the Middle East. Huntington cites arms sales from China to Syria and Iran as proof of a Sino-Islamic alliance against the West, when it is probably a result of the black market in weapons not transferred by normally peaceful countries.

Latin America, according to Huntington, is a separate “civilization” from the West, even though immigrants from Portugal, Spain, and other Western European states founded those nations. Roman Catholicism is the main religion throughout Latin America and large sections of the United States, yet Huntington does not explain why this isn’t a unifying force instead of a dividing one. Also, while India is

nonaligned with the West, that society continues to modernize, and the leaders there do not desire to isolate themselves from the world economy. If anything, trends in technology will improve conditions for India's middle class, further democratizing and opening up Indian society to Western investment. The same can be said for conditions in China and Latin America. Orthodox (Russian) culture is similar to Western society, at least since the late 19th century regarding the military alliances between France, England, and Russia. Economic associations such as the G8 cross these "civilizational" lines between the West, Orthodox, and even Japan. African culture too can only benefit from an influx of Western capital as the nations of the former third world gradually modernize. It is difficult to see how leaders of "African civilization" could see any benefit in estranging themselves from the West. Cooperation and interdependence would seem to be the more logical impulse for all nations, regardless of cultural, linguistic, or religious differences.

Huntington strives to define the new order of human civilization. He has defended this model of major cultural civilizations by asking, "If not this paradigm, how else can we describe the new world order?" As of this date, however, people throughout the world have much more in common than they have differences between them. It is in each nation's economic and national interest to increase its involvement in the global economy, as opposed to increasing barriers to international cooperation. Furthermore, it must be pointed out that nations and governments control cultures, but the reverse is not true. Huntington is accurate when he says that Islamic and Chinese cultures are gaining prominence relative to American or Western culture. Core values of those other cultures, such as the importance of religion and family customs, certainly differ from those of the West; however, any predictions of a new "cultural cold war" must be seen as alarmist and premature.

Hylobates is the sole genus of primates in the family Hylobatidae. The family, whose members are known as lesser apes, includes the gibbons (*Hylobates spp.*) and siamangs (*H. syndactylus*). *Hylobates* are called "lesser apes" due to their stature (5–12 kg) and height (about 3 feet), which are smaller than the great apes (orangutans, gorillas, chimpanzees, and bonobos: 31–175 kg). *Hylobates* species are divided into four subgenera, which are grouped together based on chromosomal numbers and coloration.

The first subgenus uses the same name as its genus, *Hylobates*, and is also referred to as the "lar group." Lar gibbons include the silvery Javan gibbon (*H. moloch*), white-handed gibbon (*H. lar*), and Kloss's gibbon (*H. klossii*), all found on various islands in Indonesia. The dark-handed or agile gibbon (*H. agilis*) occurs on Sumatra, Borneo, and the Malay Peninsula. The gray gibbon (*H. muelleri*) can be found on Borneo, while the pileated gibbon (*H. pileatus*) lives in Thailand and Cambodia. Lar gibbons have 44 chromosomes.

Bunopithecus, the second subgenus, comprises the hoolock or white-browed gibbon (*H. hoolock*), found in India, Burma, and China. Hoolock gibbons are sexually dichromatic; the males are black, and the females are tan. Females of this subgenus have whitish hairs around their entire face, while males have only white eyebrows. White-browed gibbons have 38 chromosomes.

Living members of the third subgenus, *Nomascus*, are the black gibbon (*H. concolor*) of China, Viet Nam, and Laos; the golden-cheeked gibbon (*H. gabriellae*) of Cambodia, Viet Nam, and Laos; and the Chinese white-cheeked gibbon (*H. leucogenys*) of China and Viet Nam. Members of the concolor group have 52 chromosomes.

The last subgenus, *Symphalangus*, also has 52 chromosomes. It is comprised of one species, the siamang (*H. syndactylus*), found in west Malaysia and Sumatra. Siamangs are distinguished from the other lesser apes by their larger body size (10.7–11.9 kg), throat sac, and webbing between their second and third toes.

Hylobates spp. are the acrobats of the forest, using their long arms and long, slender, and curved fingers to brachiate (swing) through the canopy. Gibbons are frugivorous, with most of their diet consisting of ripe fruit. They also eat young leaves and flowers. The diet of siamangs, however, consists of more leaves. Insects and arachnids may also comprise a small percentage of the lesser-ape diet.

Life expectancy for lesser apes is 10 to 20 years in the wild. They live in small, monogamous groups and mate year-round. Often when offspring reach adulthood (about 6–7 years), they are driven out of the group by the same-sex parent. Many usurp a small part of their parents' home range and eventually begin their own social group. The vocalizations of hylobatids are well-known and can be heard up to 1 kilometer away. The calls are used for territorial defense, among other things.

Human activities such as deforestation and poaching have caused decreases in lesser-ape populations. All species of Hylobatidae are considered

endangered, and the silvery Javan gibbon is critically endangered.

 ICEMAN

On September 9, 1991, a German couple from Nuremberg, Helmut and Erika Simon, were hiking the trails along the Niederjochferner Glacier, at about 3,200 meters in the Otzal Alps, which lie east of the Inn River along the border of Italy and Austria, when they discovered a corpse, the upper part of which protruded from the ice. In the days that followed, some damage to the body occurred from removal attempts by local authorities. But by September 23, the exposed body was wrapped, placed in a coffin, and, together with a bag full of material that had been collected at the site, ultimately delivered for study at the University of Innsbruck, Austria. It was declared a prehistoric find and represented one of the oldest and best-preserved human mummies by freezing ever found. Named “Otzi the Iceman,” after the Otzal Alps where he was found, he immediately became the object of border dispute between Italy and Austria as to his ownership. This was resolved when authorities confirmed that the spot he had been found was located in Italy. After years of study at the University of Innsbruck, Otzi was finally removed to a specially built exhibit in the new Museo Archeologic dell’Alato Adige, in Bolzano, Italy. His body was placed in a special chamber, which can be viewed through a small porthole kept at a constant 6°C and a humidity rate of 99%.

After many revisions of data and rejections of initial hypotheses, current findings concerning the Iceman’s body and possessions are emerging. Articles found on or near the body included a longbow, a quiver containing the makings of arrows, an axe, knife, a wooden-framed backpack, two bark containers, and a belt pouch.

The smooth and weathered handle of the axe was made of yew, with a metal blade inserted into the notch of the handle and tied with a strip of leather. Analysis of the axe blade revealed that it was not bronze, as had been hypothesized, but almost pure copper, with traces of arsenic and silver. According to radiocarbon dating, the Iceman died around 3300 BCE, in the New Stone Age or Neolithic period. It rendered inaccurate much of what archaeologists previously thought they knew about the people and culture of this region and gave greater insight into the Stone Age. The axe was an advanced design that was thought to be in use around 2000 BCE, when the people of the southern Alps still relied on stone for most of their tools. Revisions now needed to be made concerning the advanced stage of Stone Age man and the date of the Copper Age.

The remnants of a quiver, now recognized as the oldest-surviving one in the world, have been described as made of “bald skin,” but possibly had originally been made of fur, as there were some hairs wedged in a side seam. A wooden rod stitched onto the side of the quiver with a piece of leather gave shape to it. The top flap of the quiver had been ripped off, exposing the ends of 14 unfinished arrow shafts, 2 of which had feathers attached, together with 2 attached flint arrowheads. Also inside were wrapped four pieces of stag antler, probably destined to be fashioned into arrowheads. The bow was fractured, and the carrying strap for the quiver missing, as was the hood closure; three arrow shafts were broken, and one arrowhead was broken—all yet to be explained as to their condition. Before this discovery, scientists had not known with certainty that people had used quivers at this time.

At his discovery, it was observed that the Iceman had a primitive boot on the right foot, and grass was

Source: © CORBIS SYGMA.

noted sticking out of the tip of the boot and bound around the foot by some shredded string and some worn leather. The remains of a second shoe were also found nearby. Upon examination, it was noted that the boot consisted of three main parts: the grass insulation, a net that held the grass around the foot, and bearskin soles with red-deerskin insteps and uppers. The bottom edge of the net had loops that attached a piece of leather woven around the soles. Across the bottom of the sole was a strip of leather, probably designed to reduce slippage. With the fur side of the skin inside the sole, several holes around the insteps served as eyelets to bind the grass and uppers tightly.

Into these boots were tucked leggings made from scraps of fur sewn together that reached nearly to the groin. A fur tab found inside the boot and a second one sewn onto the edge of one of the other garments indicated that these were not real pants, but suggested that the mechanism for attachment was analogous to garterlike straps and stockings. The Iceman would slip his feet through the tubular “leggings” and cinch it around his thighs with a leather strap through openings along the tip of the legging. A strap extended from the front of each legging up to his waist, where it was attached to a belt that secured his loincloth. The whole outfit was so unusual that no prehistorian had ever seen or predicted these leggings and attachments.

Another garment had to have covered the torso, and remnants of it suggest that the article was likely a

huge fur coat or cape of some kind, but with no evidence of sleeves or collar remaining; this interpretation remains open.

Topping all of these clothes was a long cape of plaited grass ending past the knees. It was made of long bundles of grass arranged vertically parallel to one another and bound together at short intervals by two twisted grasses plaited horizontally. The lower part of the cape was not plaited, allowing the grass to hang freely in a long fringe. A bearskin hat completed the outfit.

A knife had an approximately 7.5 cm blade made of gray flexed flint common in Europe. The actual length is unknown because the tip had been broken off. The edge of the blade was serrated, resulting from retouching, a kind of sharpening in which small pieces are broken off using a bone or antler as a tool. It also had a polish on the edge of the blade from cutting grass. Among the other artifacts were a finely woven grass sheath nearly matching that of the knife blade. A grass string coming off the handle may have aided the Iceman in carrying it.

A leather pouch attached to a long leather belt worn around the waist and under the coat was in a position like none other ever seen from prehistory. The contents could be accessed through an 8 cm gap along the top seam or laced shut. The pouch contained three flint blades of different types, a piece of hollow goat or sheep bone, and the rest of the small space filled with a wad of tinder bracket, *Fomes fomentarius*, a few hairs, and traces of pyrite. By keeping the pouch inside his coat and next to the skin, Otzi had found an effective way to keep his kindling dry.

Other artifacts of interest included a leather tassel threaded through a white marble disc, a wooden object from which protruded an antler bone, and two pieces of fungus punched and threaded onto strips of leather. Both pieces of fungus were identified as *Piptoporus betulinus*, a birch polypore, a common type of mushroom that grew on birch trees. These fungi were speculated to possibly have some

medicinal value, while the antler bone was thought to be a retoucher.

Remains of 17 types of trees and shrubs have been identified so far among Otzi's belongings. The bark used to make his containers was composed of white birch, the longbow and axe handle of yew, and his knife handle of ash. The arrow shafts were fashioned from viburnum and cornus. The backpack frame was of larch and hazel. Leaves of Norway maple and juniper were used as the insulating material for the charcoal embers carried in one of the containers, while the fuel was composed of a mixture of willow, alder, spruce, pine, and elm. All of these, together with his layers of skins and grass revealed the uses of the natural environment some 5,300 years ago.

Otzi's body has undergone extensive and intensive study. Originally thought to be a person who had recently died in a mountain climbing or hiking accident, the corpse was subjected to rough treatment trying to free it from the ice. When using a nearby stick (his bow) failed, a jackhammer and ice pick were used, damaging the clothing and drilling a hole in his hip. Compounding the problem, his left arm was broken trying to force the body into a coffin. Upon verification that this was an archaeological find and with the stabilization of the climatic conditions in the laboratory, a series of tests were initiated that could possibly reveal injuries, disease, and any physiological abnormalities. X-rays and CT-scans that produced cross-sectional images, each millimeter wide, confirmed the damage to the left hip, buttock, and thigh area that had been obliterated by the rough removal attempts. The heart, lungs, stomach, intestines, liver, and kidneys were dissected and shrunk to almost nothing, with the brain reduced to the size of a fist. The CT-scans also revealed that the abdominal and carotid arteries were heavily calcified, denoting arteriosclerosis; rather surprising, since Otzi, at his death, was determined to have been in his 40s.

The organs were so dissected that a standard autopsy was ruled out, and samples of tissues were the only means of investigation. Microscopic analysis of a small sample of semidigested food was removed from the transverse colon. The position and progress of the food indicated that the Iceman's last meal had been eaten about 8 hours before he died. It consisted of a mass of material made up of einkorn wheat, one of the few domesticated grains grown in this part of the world during the Iceman's life span. Its presence indicated contact with an agricultural community

common in the Neolithic period of prehistory, in which people lived in semipermanent settlements, raising animals and engaging agriculture. The preponderance of bran, the outer skin of the wheat grain, suggested that the wheat had been finely ground and made into a flatbread. In contrast with modern breadmaking using yeast, which requires a high level of gluten in order to rise, einkorn wheat contains low levels of gluten, so the bread was unleavened, tough, and hard. If the einkorn had been eaten whole or boiled, then whole or larger pieces of the grain would have been evident. In addition, small particles of charcoal, which came from the wood of conifers, were found attached to the bran, indicating some sort of baking process. Examination under the electron microscope revealed tiny muscle fibers and a burned bit of bone and suggested that the Iceman had also eaten meat, together with some plant material. Other contents of the sample included the eggs of the parasitic human whipworm, *Trichuris trichiura*, which produce symptoms of stomachache and diarrhea after infestation. These could be ingested via plant material or the intake of water.

Many different varieties of pollen were detected on the clothing and in the colon sample. These durable grains contain a record of the Iceman's surroundings at the time before his death. When studying pollen samples, the pollen grains generally are examined as to their method of transmission, type, and range, and then compared to various locations in the proximity of the site. In this sample, the preponderance of pollen was that of the hornbeam. The remarkable preservation of the pollen gametophytes indicated that the pollen must have been released from the trees concomitant with ingestion, because if they had remained longer in Otzi's colon, then they would have decayed. This observation, together with the fact that the pollen was of the spring blossoming varieties, meant the downfall of one of the hypotheses surrounding his death—that he had succumbed after being caught in some early blizzard in the fall, as no autumn blossoming varieties were present in the colon.

Corroborating evidence came from a sample organic material that had been excavated near the site. A wad of 14 maple leaves, one wrapped inside another, revealed tiny chunks of charcoal, together with some spruce and juniper needles and birch bark pieces. The maple leaves were missing the stems and, when tested, still had chlorophyll in them, indicating

that they were removed from the tree sometime in the spring of the year. If they had been picked in the fall, either from the ground or the trees, the stems would be present and the chlorophyll missing. Further investigation implied that the leaves had been stripped from the tree in the spring in one swift fashion, leaving the stems on the tree.

Fourteen sets of bluish-black marks on the Iceman's back run parallel to the spine in four groups of vertical stripes varying in length from 2.8 to 3 cm and in width from 2 to 3 mm. Further down the body, on the inside of the Iceman's right knee in the shape of a cross, was another tattoo, repeated on the lower-left ankle.

Although Otzi's body was discovered in 1991, it was not until 2001 that new X-rays were taken, studied, and subsequently revealed that a flint arrowhead had hit the Iceman in the back, moved upward, shattering the shoulder blade, and was embedded on the left side of his chest within a few centimeters of the left lung and about 10 cm from his heart. The wooden arrow shaft was missing, but probing confirmed the presence of an entry wound that had not had time to heal.

Computerized tomography (CT) has further revealed the damage done to nerves and major blood vessels, paralyzing his left arm and causing major internal bleeding, contributed to his death. He had also received cuts on the hands, wrists, and rib cage. Many theories abound concerning the actual scenario surrounding his demise.

DNA tests have resulted in further complications and new speculations about the Iceman's final days. Samples of blood taken from the antler-skinning tool, arrows, axe handle, and coat revealed they were from four different DNA sequences: one on the knife blade, two different ones on one arrow, and a fourth on the coat.

Samples of the Iceman's tooth enamel, bones, and minerals, which came from the food via soil and water, have helped establish a probable location of Otzi's childhood. Similar analyses were made from the minerals in his adult bones and compared with a wide area of the Tyrolean Alps. Together with botanical evidence, it appears that the Iceman's early home was to the south of the find but most of his adult life was spent somewhat more in the northern valleys.

Speculation and research continue to change the interpretation of all aspects of Otzi's life, health, use of his environment, and the circumstances of his

death. His contributions to the understanding of early man and his place in nature have been far-reaching and significant. Science, as the best-tested information that is presently known, is continuing to be validated, and with further study and increased technologies made available, a more refined picture will result.

The term *ideology* is etymologically divergent. A derivation from the rarely transmitted Greek *ideología* (opinion, discourse) must be denied due to the extremely differing meanings of the term today. *Ideology* rather derives from a combination of the Greek nouns *eídos* (appearance, form, term, imagination, idea, archetype) or *eidōlon* (picture, illusion, idol) and *lógos* (speech, doctrine, reason) and hence represents a scientifically sound examination of human ideas, which are naturally imperfect. Francis Bacon's "theory of the idols" is founded in the human mind, with its idols (pictures, imaginations) that are innate or input, although it has not much in common with the modern term ideology. With ideology in the broadest sense, we mean system of conceptions or ideas that are not based on revelation, but made by man. Therefore, ideology can in that sense mean a "system of ideas or history of ideas."

Terry Eagleton characterizes ideology in general as

- (a) the process of production of meanings, signs and values in social life; (b) a body of ideas characteristic of a particular social group or class; (c) ideas which help to legitimate a dominant political power;

(d) false ideas which help to legitimate a dominant political power; (e) systematically distorted communication; (f) that which offers a position for a subject; (g) forms of thought motivated by social interests; (h) identity thinking; (i) socially necessary illusion; (j) the conjuncture of discourse and power; (k) the medium in which conscious social actors make sense of their world; (l) action-oriented sets of beliefs; (m) the confusion of linguistic and phenomenal reality; (n) semiotic closure; (o) the indispensable medium in which individuals live out their relations to a social structure; (p) the process whereby social life is converted to a natural reality.

Ideology does not necessarily signify “the dominant forms of thought in a society,” but it is the fundament of thinking and therefore constitutional for “a particular social group or class.” Consequently, Eagleton centers in his definition of the term its power to integrate, which in most cases aims at political rule or social dominance.

Ideology therefore pursues worldly aims mostly on a political or economical level. In that, it demands ideological neutrality and represents itself as objective theory; it does not actually want to be ideological. Ideology does predominantly serve a certain *weltanschauung* (worldview), though. This can be seen quite clearly in the modern development of the term ideology since the French Revolution and the times of Napoleon I: With Antoine L. C. Destutt de Tracy in 1801, it meant a certain philosophical or political doctrine for the very first time. Ideology often connects secular interests with religious language and symbols, in order to strengthen its own position and to have an effect on people without losing the secular context completely. The unlimited realization of its purposes, while not thinking about the moral value of its methods, is the aim of ideology. It strives for a realization of salvation, in order to win people’s favor with their doctrine.

Time and world and man are to be changed by ideology and to be seen in a different light. In that, a field of tension between present and future becomes discernible, which releases powerful, sometimes even revolutionary energies. Ideologies often have totalitarian features, as no totalitarian regime can live without ideology or without ideologization of its political ideas. The expectation of salvation and the benefactor in such systems prove to be a political messianism that gives people the strength to believe

in the ideology of these political systems. With this kind of devoutness to ideologies, many people are monopolized, won totally, whereby such political systems develop totalitarian effects and become totalitarianisms.

It is an important task for ideologies to find new myths, especially myths about the origin of a nation or people, and consequently implant the newly created tradition of the ideological *weltanschauung*. Based on such new myths and fake traditions, a specific newly created culture can develop, as we can see in the images. These images integrate ideology in everyday life of people. Therefore, they even build an individual form of cults and feasts. In this fake-liturgical and ritual style of celebrations, National Socialism celebrated the sacrifice as self-sacrifice. Ideology is therefore mostly based on a constructed myth and artificial traditions. It gives a utopian aim to its followers that proposes salvation. The totalitarian system with its leader at the top, whose requests the crowd has to follow, whatever they express, leads to the beneficial intention. Without the crowd following their leader’s requests, the beneficial destination would be endangered.

Paradoxically, ideologies do definitely not want to be regarded as religions, and in consequence, present themselves accordingly. The strengthening of the religion, though, can preserve from seductions of worldly ideologies. The totalitarian regimes let lose their forces in creating a short-lasting connection between the overcoming of this life and the salvation of mankind. Here, the power of utopia plays a big role, as it is important for the realization of inhuman ideologies because of the alleged paradisiacal final condition. Every ideology needs a specific utopia. Religion is regarded as an obstacle and is consequently monopolized, removed, or simply pushed aside, as it competes with the totalitarian ideology and has the same universal claim. The totalitarian ideologies are mostly atheistic and materialistically orientated. They are the base for objectification and dehumanization of the enemy, the *Volksschädling* (parasite), which is only mass and matter and can be eliminated industrially and with machine, for welfare’s sake.

Ideology follows the compulsory maxim this way and not any other and is based on only one (political) truth. Both are very important for the totalitarian thinking. This criterion of truth is totally subject to the ideological propaganda. At the same time, political ideology is normally proclaimed as a salutary

political doctrine that can solve the actual critical state of affairs. This political ideology is represented by one party, which very often is personified by one person only. Ideology and utopia too serve as a motor for totalitarianism and support its enforcement. Hannah Arendt sees in political ideology that is being spread and popularized by propaganda one of the most important features of a totalitarian system. In Carl Joachim Friedrich's and Zbigniew Brzezinski's theory of totalitarianism, ideology is also put at a structurally important place. Hannah Arendt emphasizes not only ideology, but terror as supporting pillar of totalitarian tyranny, like Eugen Kogon before her. A totalitarian ideology, as Marxism or Fascist and National Socialist ideologies, for example, never ceases to announce the desired final state in a prophetic way. To get over the current state of affairs, it uses all forms of power and violence. Historical and religious facts are connected and are used for secular prophecies, as one can see in Hegel's philosophy and in its completion by Marx and later, in a different form, with Max Weber. Jacob Taubes is right in connecting Joachim da Fiore with Hegel, whereby the tension between religious and secular aspects in history are recognized quite well. This field of tension influences in a special way the intellectual milieu in Europe at the beginning of the 20th century, which in one way or another smoothed the way for both world wars.

Ernst Bloch makes out *The Spirit of Utopia* (1918) in the ideologically tense time and political situation at the end of World War I, leading into the first half of the 20th century. The utopia presents the positive aim that makes the realization of totalitarian ideologies bearable and permissible. So ideology gets the opportunity to countermand the critical awareness of the people in some way. In that, it shows a big resistance and permanence; one could say ideology sticks like pitch, it is very long lasting. Without the power of utopia, the totalitarian ideology would not be able to display its effects, because nobody would be ready to carry out its cruel sanctions and to put into practice the mass destruction in factories of death. Only with utopia do ideologies have the power to drive their men, despising aims and their inhumanity, because the goal of a harmonic ideal state that one has never seen is proposed. With the help of utopia, totalitarian ideology creates a new image of man that does not accept any universal humanity and so denies the nature of mankind. To be human cannot, as a matter

of course, be awarded to everyone. So the human is being defined and judged in a new way.

Norman Cohn sees the driving power of medieval mass movements more in common need and common fate, like poverty or epidemics for example, than in a worldly ideology. Secular ideologies were too weak in medieval Europe to be accepted against the predominant doctrine of the church. Cohn's and also Talmon's works show that the research of militaristic and messianistic movements in the 1940s and 1950s were very important, because of the disastrous, fresh impressions of World War II. Very often one misses that the church did not by any means forbid a reasonably processing research. She only fought against the self-idolizing attitude of man, who saw himself, following the *homo-mensura* sentence of Protagoras, as the center and measure of all things: Man is the measure of all things: for the being that they are; for the not-being that they are not.

The biased ideology, which is oriented to certain interests of power, follows the truth neither of revelation nor secular reason and so draws a distorted image of reality. A world that closes itself more and more in itself holds necessarily the dangers of ideologization, as Romano Guardini in the 1920s and 1930s, being in Berlin, was aware of. Ideology supports, with its wrong understanding of world and reality, a wrong *weltanschauung*. The center of all knowledge, of all wisdom and of the truth cannot be grasped by humans alone; it is and will always be never ending and divine. Guardini said in his inaugural lecture in Berlin, 1923, that the church did by no means forbid the discovering in whatever part it may be, not even in the center of everything. The church allowed it and was happy that man wanted to do so, but drew people's attention to the point, however, that this center may not necessarily be reached in this life. Ideology did, in contrast to that, not in any way limit the cognition of man. Nothing in the world or in man was, according to the ideologies, undiscoverable.

By denying the belief in Trinity, ideologies destroy the center of Christian religion. That means ideology shows in its naturalistic features a seeming omniscience, but it adopts no kind of transcendent model. The model of an ideology, be it nature, history, or a certain race, is a worldly quantity that has been lifted to a *Realissimum*, in which man is reflected. That leads to self-idolizing of man in ideology. Gnostic sect movements of Late Antiquity, the Manichaeism for example, and Christian sects of the Middle Ages, the

Waldensians and the Cathari, supported with their views the ideologies of modern age, which are characterized by their belief in sciences and a strict dualism between the kingdom of good and the kingdom of evil. In this context, it is interesting to see that Raymond Aron especially points out the Manichaeistic, strictly dualistic character of modern ideologies when describing political/secular religions, as they see everything that is good in their own teachings and the evil in everything that does not support their views. Harald Strohm also refers in his portrayal of National Socialism as gnosis to its Manichaeic features. He further deals with the *gnostic mythology* of National Socialists and analyzes Hitler's psyche, which can be compared, according to Strohm, to that of a gnostic leader, that of Mani, for example. One can also see these gnostic features in the secular doctrines of salvation of the totalitarian ideologies whose logical consequences were the extermination of dissidents and the cancellation of mental freedom. Hans Blumenberg looks at the unvanquished gnosis from a contemporary point of view in a quite similar way as Voegelin. Alan Besançon arrives at this conclusion as well. He claims that ideology that was in terms of content a *perversa imitatio* of science, was in terms of form a *perversa imitatio* of religion. And as its fundament stained by gnosis and idolizing stood in contrast to Christianity, ideology did constitute itself as counterchurch with its countercouncils, counter-popes, and so on.

Besançon does not go as far as to regard ideology as political or secular religion. The reason for it is that persons who follow an ideology can feel the religious character and consequently show an attitude toward ideology as a religion. Ideology is thus no secular religion, as it is not recognized as one by its followers. Furthermore, ideologies are in nearly all cases antireligious or atheistic. For this reason, people in countries with ideologized regimes, and after their decline, need an inward reform to reshape their lives and to resist the dangers of relativism, as the development of Eastern Europe showed after the decline of the communist system. In that way, they do not have to flee in the cul-de-sac of an ideology, but can live a self-responsible life. In this case, religion can work as an effective shield against the secular ideology, which wants to monopolize them totally and makes it impossible to confess one's religion in freedom.

This is why, for many Christians, the way into resistance was the only answer to totalitarian heresies,

called ideologies. In that way, the untruth of ideologies that pervert the truth and constitute themselves as doctrine of salvation becomes clear. Raymond Aron analyzes this religious dimension of 20th century political ideologies in his concept of a political/secular religion.

Aron predominantly examines the phenomena of totalitarian tyrannies in their religious quantity, especially in their self-redeeming character. The political/secular religion represents its ideological content as doctrine of salvation. The concept of political religion clearly shows that ideologies of totalitarian regimes are founded on secular ground. Ideology, however, as originally political doctrine becomes related with religious features, as the religious interest of man nearly imperceptibly leads toward these ideologies. At the same time, church and religion are weakened and marginalized, sometimes even persecuted. The people's interest in salvation is focused on genuine political theories, which means that ideologies are distorted images of religion, that is, a negative reflection of religion, which is a *religio falsa*, in the Augustine sense of the word, or "a *perversa imitatio* of religion," as it is called by Alain Besançon. At the same time, the development of ideologies out of the mainstream of political ideas shows religious features. Ideologies often develop like Christian heresies of the Middle Ages did. They found a way to stand out of the mainstream of Christian doctrine: to absolute a part of the total doctrine, which led to a schism from the original theory.

In this way, it is completely appropriate to define the totalitarian ideology as *political heresy*, as it separates itself from the mainstream of political ideas. Ideology generally already shows in its development features of a religion, and it behaves like heresy in politics. Eric Voegelin confirmed this statement in his work *The People of God* (about 1940). He arrived at the conclusion that the church was, approximately since the year 1300, no longer able to integrate eschatological and gnostic splinter groups, which is important for the preservation of its authority. In consequence, revolutionary movements developed, which led via the Protestant reformation to further schisms. This development finally revealed its secularistic, anti-Christian character and culminated in political mass movements of the 20th-century totalitarianisms. According to Voegelin, totalitarian systems and their ideologies show features of political heresies.

Karl-Dietrich Bracher is of the opinion that the breeding ground for ideologies of the 20th century was built at the beginning of the century. New political-religious tendencies developed in relationship to racial conflict and class conflict movements toward a nationalistic ideology that finally led to totalitarianism. It was during this period of time, as well, that political religions emerged, which, according to Bracher, were established artificially: were *created*. Political religions are pseudoreligious ideologies, demanding a scientific validity as well as a religious absoluteness. They promised to unite what was separated through modern science and secularization and to harmonize them with culture and technology, with politics and culture. In doing so, they tried to promise everybody everything, to be collective movement and collective faith and at the same time, to be in strong confrontation with an absolute ideological enemy: an ideology of integration and hostility in one.

Claus-Ekkehard Bärsch makes it clear that National Socialism used in its ideology the power of religion to guide people's actions to lead the broad mass of people into the direction of its doctrines. According to Bärsch, imagination, faith, wrong consciousness, lies, nonsense, and mania became the realities that influenced the way people acted. The terms *people*, *nation*, *race*, *Third Reich*, and *anti-Semitism* have religious implications. They are based on a feeling of being chosen, on an honor and a priority of the Germans, in contrast to other peoples or persons who have to be exterminated as they stand in contrast to the chosen, and as such are regarded as evil.

Bärsch already recognizes in this fact an important feature of a political religion. He points out that if you assumed an extraordinary relationship with God which can only be the own collective in the qualification of the own collective, the fixation of the own identity in contrast to other people, the New Socialism-ideology would correspond to the content of a political religion. Different from an ideology in form of a political religion or a political messianism, the relationship between religion and politics, channeled in civil religion, does originally not portray an ideology, as it is stated by Jean-Jacques Rousseau in the first version of *Contrat social* (1760): You have to think like me to be saved. This is the terrible dogma, that destroys the earth. You have done nothing for public peace, if you do not expel that diabolic dogma from the republic. Whoever does not think of it as disgusting, can neither be a Christian nor a civilian nor a

human being: he is a monster, who must be sacrificed for peace of mankind's sake" This form of criticism of the ideological thinking and the consequence, not to allow such ways of thinking in a free system, can especially remind us of terrifying omissions in free European states of totalitarian ideologies in the second half of the 20th century. So, the criticism of ideologies, which has, according to Hans-Georg Gadamer, its base in the hermeneutics as well, is an important task for the philosophy. Many supporters of the Frankfurt School have vouched for criticism of ideology as well: Theodor W. Adorno, Max Horkheimer, Herbert Marcuse, and, last but not least, Jürgen Habermas. Karl Jaspers regards ideology as a kind of *modern sophistic*, which manipulates people not least by language. So do, in a similar way, Victor Klemperer in 1947 with his book *Lingua Tertii Imperii* (Language of the Third Reich); George Orwell with "Newspeak" in his novel *Nineteen Eighty-Four* (1949); and Josef Pieper and Alain Besançon with the ruin of the language by ideology, which has its own manner of speaking. An influential literary review of ideology and propaganda of the totalitarianism and of the events of World War II follows in the collection of essays *The Captive Mind*, by Czesław Miłosz, published in Paris in 1953, in which he sharply attacks the Polish communist regime. The concept of political religion takes on an especially important role with regard to the people's growing sensitivity toward totalitarian ideologies, as it does reveal symptoms of totalitarian ideologies. In this point it is also possible to strengthen the circumspection of people toward dangerous ideological *weltanschauungs*. It will never be possible to prevent the influence of ideologies completely, as their attracting power, by which many people will always be confused, remains virulent.

Man is *homo religiosus*. His nature is deeply shaped by the pursuit for the absolute and transcendent. This religious pursuit needs necessary satisfaction, be it in a traditional, historically grown religion or in a secular ideology that leads to terror and destruction. Man always stays unready in the search for happiness and salvation on earth, as, according to St. Augustine (*Confessiones*), true salvation that will not be given by any worldly movement; it can only be found in God: "Restless is our heart until it rests in Thee [my God]."

The Ik are a hunter-gatherer and agricultural group who live in the Morungole mountains, around the Kidepo Valley, in northeastern Uganda. They are few, numbering several thousand, but are famous within anthropology because of Colin Turnbull's extraordinary book *The Mountain People*, for which he was roundly criticized within anthropology. Turnbull is perhaps the only anthropologist to conclude his study with a recommendation that the group he studied be destroyed by being forcibly resettled into small units throughout the country.

Turnbull worked with the Ik in the mid-1960s. While he was there, a severe drought struck, making living conditions difficult. Moreover, the Ik's livelihood had been adversely affected by their recent eviction from the Kidepo National Park. Turnbull's book is a devastating and horrific account of a society that is both falling

apart and willfully destroying itself. He describes scenes in which handicapped children have their food stolen from them by their peers and are eventually locked up in their home and left to die by their parents; where elders fall into gulleys and are laughed at and mocked by their fellows; where family members fight to strip the ornaments from their dead relatives; and where sisters steal tea from their brothers as they lie dying of gunshot wounds inflicted by cattle raiders.

The book was poorly received. There was a general feeling that the Ik were being badly represented by an anthropologist who had come to hate them. Perhaps the kindest comment was that this was an account that could best be understood as describing the consequences of the drought on the anthropologist, not the Ik. Turnbull was later criticized by Heine, who found many faults with his understanding of the language and his interpretation of events. Heine suggested that the disturbing events Turnbull saw were really the product of his own malevolent attitude.

Turnbull's account lives on, however, in literature about the consequences of protected areas on rural groups. It is taken as an early case of a detailed description of what can happen to people when they are denied access to rural resources by conservation. This literature is marked by its uncritical use of Turnbull's work, ignoring both the critiques of his findings, Turnbull's own conclusions, and the complex idealism that defined Turnbull's work.

The incest taboo, considered a universal taboo, forbids marriage or sexual relations with a close relative.

However, there are problems with any definition of the incest taboo because the definition of “close relative” varies tremendously among different cultures, the taboo is universal only with very inconsistent applications, some writers restrict the definition to opposite-gender relations, and there are major violations, whatever the definition. Behavior that is strongly, perhaps even fanatically, forbidden in one culture might be accepted, encouraged, or even expected in another culture. Where the taboo is enforced, punishments have ranged from social ostracism to banishment, imprisonment, or death.

There are four inconsistent theories that attempt to explain the taboo’s existence. Claude Lévi-Strauss and others have suggested that the taboo exists to encourage people to marry into other groups (exogamy), in order to build social, economic, or political alliances with other groups and thereby increase the group’s ability to survive and expand. This theory applies particularly to ancient societies when most people lived in small, often isolated and vulnerable groups.

Lewis H. Morgan and others have suggested that sexuality with close genetic relatives can increase genetic diseases or other problems. In actuality, historically, people usually did not understand how genetics affected reproduction. Among modern Western cultures, this explanation is still strongly believed, although modern genetic research does not always support this belief. Genetic problems are more likely to occur in a closed group that inbreeds for several generations than in a onetime, close-cousin reproduction. Moreover, about half of the prohibited incestuous unions in the world have been with genetically unrelated people (e.g., an in-law of some type).

Bronislaw Malinowski and others have said that the incest taboo exists to prevent social role confusion or conflicts within a family, particularly regarding parent–child and sibling roles. Edward Westermarck and others have said that close family members have an instinctual repulsion toward incest, but other theorists suggest that an instinct of such strength would not need a strong cultural taboo. Other researchers point to the frequency of incest despite the cultural taboo or argue that living closely together as in a family leads to the opposite of incestuous desire (referred to as a “habit of avoidance”).

Parent–child and brother–sister incest is the most strongly prohibited, partly because of the assumption of unequal power relationships. In the United States, beginning in the 1970s, largely as a result of

encouragement from feminist theorists and conservative voters, this has been a major area of concern, with fervent encouragement of very severe punishments.

There have been several royal families (Egypt, when part of the Roman Empire, the Inca empire, and precolonial Hawaii) that required brother–sister marriages, primarily to maintain the family’s unique sense of divinity. Also, in Egypt, brother–sister marriages were practiced by 15% to 20% of the farming class. First-cousin marriages are legally forbidden in some states in the United States, but practiced in others, and in some Middle Eastern and North African cultures, first-cousin marriages are common. Some preindustrial societies encourage first-cousin marriages for cross-cousins, but not for parallel cousins. Some groups (e.g., Sephardic Jews), have encouraged first-cousin (and uncle–niece) marriages at critical points in their histories. The reasons for the incest taboo have long been, and continue to be, a major debate within anthropology.

INDIA AND EVOLUTION

The term *evolution* comes from the Latin word *evolvere*, which means *to develop* or *to unfold*. It is equivalent to the Sanskrit word *vikas*, which means more than growth. It describes a series of related changes in a system of some kind. It is a process in which hidden or latent characteristics of a thing reveal themselves. It is an order of change, which unfolds the variety of aspects belonging to the nature of the changing objects. Out of various theories of origin of society—like divine origin theory, the force theory, the social contract theory, the patriarchal and matriarchal

theories—the evolution theory offers what we think a generally correct explanation. According to it, the society is the result of a gradual evolution, in that it is a continuous development from unorganized to organized, from simple to complex. Various factors helped in this process. For example, kinship and family were the earliest bonds uniting man with man.

It is generally assumed that the ancient Hindus in India lost themselves so much in speculating over the abstract metaphysical problems of the ultimate nature of worldly things that they never exerted any serious thinking in connection with the more practical and worldly problems, like those of social organization and evolution of society. In fact, they had given serious attention to the problems connected with social organizations, and a system or scheme of social relations has evolved for securing the best possible organization of human life and conduct that they could think of.

A society with all forms of social organization and institutions emerges out of human needs. The human needs define human interests, purposes, and aspirations; and the actual planning or devising different forms of social organization takes place in adjustments of human behavior, individual and social, with these purposes and aspirations. The Indian conception of life and its conduct is also organized in view of these considerations. The fundamental meaning of life and existence as understood by the Hindus permeates through all the forms of social organization, which are intended to regulate and direct the conduct of individual's life. Therefore, our first task will be to narrate and understand Hindu's fundamental conceptions regarding human existence as a whole, its purposes, its aspirations, and its mission.

According to the Hindu, this life alone would have no meaning; it has meaning only as a link—even if the last—in a chain of births in the past and in the future; it is a stage of transition from past births toward future birth(s), unless *Moksha*, or final liberation, is obtained within the span of this life. The soul of a man is, for the Hindu, immortal; the bodies in which he lives during the stages of transition may change. This fundamental idea persists through the whole of the Hindu life from earliest written literature Vedas to today. Indian social thought is shaped in the system-forming endeavor to metaphysics of transcendence since the Vedas more than 40 centuries ago. Whatever might have been the specific socioeconomic conditions in which the creative

genius of the Vedic period flourished, approximately 3000 BC to 5000 BC, its influence on the evolution of the Indian society has never waned. In the Vedic literature, including the Upanishads, spontaneity, poetic imagination, and sense of gravity of the fact of existence surpassed intellectualism. Perhaps that is why India, notwithstanding her sociopolitical-economic changes, retains its weary mood eternally, a mood running more after the other-worldly and inane than after the empirical and the concrete.

There are two ideological concepts in Hinduism that reveal two aspects of life: the goal of life and the means to achieve that goal. The Hindu view of life can be best brought out by a theory of fourfold objects of life (*Purushartha* theory). According to this theory, there are four *Purusharthas* or aims of life: *Dharma*, *Artha*, *Kama*, and *Moksha*. *Moksha* represents the end of life, the realization of an inner spirituality in men. It means that the true nature of man is spiritual and the mission of life is to unfold it and derive thereby the meaning and joy of it. *Artha* refers to the acquisitive instinct in men and signifies his acquisitions, enjoyment of wealth, and all that it connotes. By according *artha*, a place in the scheme of life, Hindu thinkers applauded the pursuit of wealth as a legitimate human aspiration. *Kama*, the satisfaction of the instinctive life, is recognized as one of the aims of marriage, along with dharma and procreation. Hindu thinkers tried to assign a place of sex in the life of men. But *kama* does not mean only an instinctive life; it means emotional and aesthetic life as well. *Dharma* provides a link between the two, the animal and the god in men. *Dharma* is knowing that *kama* and *artha* are means and not ends to *Moksha*. A life that is dedicated to the unrestrained satisfaction of these urges is undesirable and even dangerous. It is consequently necessary that it should be regulated by the ideal of spiritual realization, dharma.

The theory of *Purushardha* is given concrete expression in the Hinduism's scheme of *Ashramas*. According to this scheme, life is divided into four stages: *Brahmacharya*, *Gruhastha*, *Vanaprastha*, and *Sanyasa*, with every stage having its own duties and functions. An individual enters to the stage of life, *Brahmacharya*, by the performance of initiation rights. This ceremony initiates man into disciplined life. The initiation rights mark the beginning of schooling, where study is an important duty in a person's life. Besides intellectual equipment and disciplined life, the training in character and ethical life

are necessary. A student should learn to restrain his senses. In this control of senses, the control of the sex instinct is prominently stressed, and every individual going through this stage is expected to observe complete celibacy. Men thus learn his proper dharma in the first stage. The second stage of life, *Gruhastha*, is the life of a married man. The aim of marriage, according to Hindu philosophy, was dharma, progeny, and sex. Personal gratification is one of the ends of marriage, but a last place assigned to it clearly indicated that it should not be the guiding rule of life. Marriage is more a social obligation, as its main purpose is the performance of dharma and the perpetuation of family, as well as the continuation of the group through progeny. On entering the third stage of life, *Vanaprastha*, men continue to perform all the duties of the second stage. But the achievement of this stage lies in the discipline that prepares a man finally for the renunciation of familial ties and social relations. All the bodily comforts have to be gradually dispensed. This austerity is eminent to cultivate in man indifference to his own body. The last stage of life, *Sanyasa*, is the life of an ascetic. The Hindu ideal of life is Moksha, and that can be achieved, according to the Geetha, by cultivating detachedness to worldly things. The duties of this stage are mainly defined with the purpose of attaining this state of detachment.

In this ideological scheme of *Purusharthas* and *Ashramas*, the evolution of life is approached from the point of view of training or nurture of the individual through specifically provided environments at different stages of life; while on a structural scheme of *Varna-Caste-Organization*, the evolution of life is considered from the point of view of the larger group, and the individual's position is defined in the group with reference to his innate nature, his tendencies, and disposition.

Hindu society evolved in highly structured caste system. There are many studies about the origins of caste system. One racial theory of the origins of caste talks about the unadulterated and pure blood of *Aryan* race. However, other explanations endorse the view that caste is mainly occupational in origin. Occupations, which were organized into guilds, became exclusive and stratified into castes. The word *Varna* is practically all the pure-blood race theorists have in support of their position. They conclude that the difference in color is one of the causes that lay at the foundation of the caste, for the caste originated from *Varna* (color) organization. As a matter of fact, however, in Sanskrit,

the word *Varna* means appearance, exterior, color, kind, species, caste; and Manu has used *Varna* synonymously with *Jati*, which means birth, the form of existence determined by birth, position, rank, family, descent, kind, and species. The theory of the origin of *Varna* from the various parts of the creator's body also finds a place in the early scripture of the Indian social thought.

For the historical treatment of *Varna-Caste* system, the history of India could be divided into four periods: first, the *Vedic* period, ending about 600 BC and comprising the literary data of the *Vedic Samhitas* and *Brahmanas*; second, the post-*Vedic* period, extending to about the 3rd century of the Christian era; third, the period of the *Dharma Shastras*, which ended during the 11th century AD. Manu, Yajnavalkya, and Vishnu are the chief exponents of the social ideals of this period. The fourth, modern period began during the beginning of the 19th century. The customs and beliefs of the contemporary Indian society were mostly fixed and classified by the thinkers of this period. During this period, the present-day vernaculars of India were evolving.

In the *Rigveda*, the earliest literature of the first period, three classes of the society are frequently mentioned, *Brahma*, *Kshatra*, and *Vis*. The origin of four classes (i.e., the addition of *Sudra* to these three) is repeated in most of the later works of this period. These four classes are described as being of divine origin, and these classes or orders are regularly referred to as *Varnas*. The literature of the post-*Vedic* period, while reiterating that there are only four *Varnas*, mentions certain mixed castes and also a group of outcaste class. The importance of sacrifices and ritualism had been growing, as well as the prestige of the priest, and the creator is said to have apportioned the duties and function of the four castes according to the inherent qualities and capacities of individuals. This period testifies to the rigid stratification and internal solidarity of the four *Varnas*, and the rules and regulations governing social life and individual conduct differed according to the *Varnas* to which they belong in the society. The third period of Indian history is marked by two developments in ideals of the Hinduism: first, the glorification of the gifts to *Brahmins* and, second, schematic growth of imaginary hells as punishment for certain offenders and the progressive application of the doctrine of rebirth. The solidarity of a caste as a unit of social organization was more and more acknowledged.

Gradually, then, the caste system became ordered and stabilized, with priests giving religious interpretation of all questions of the moment.

From this system of *Varna* organization, new castes came to be formed: (a) by groups separating from the present body and migrating to areas out of the range of normal communication; (b) by occupational changes within the caste; (c) by religious schisms; (d) by fragments from other caste grouping about some common objective; (e) by the offspring of crossings between two or more castes or by sex. When a new caste is formed and established, it will originally claim specialty in some vocation, and it will claim distinction on the basis of some fictitious or real cultural heritage, which it will always try to guard. Thus, caste has been a potent factor in stabilizing the cultural pattern of India. Village life was so coordinated that every caste has its proper place and duties. The joint family system is another potent factor in the continuance of cultural traditions. The traditional authority of the head over the junior members of the family was so awe inspiring that the juniors never thought of expressing their differences, whatever their convictions might be. The subordination and superordination designed to regulate the lives of different members in the hierarchy of the joint household, recognition of the family as a unit for all social relationships, and the place assigned to the family as a judicial unit in family quarrels all tended to give the family such enormous influence that the individual lost his identity in it. The social environment made the individual feel that he had no interest apart from those of the family.

India occupies a center stage in human evolution. It has served as a major corridor for the dispersal of modern humans, which started from Africa about 100,000 years ago. The date of entry of modern humans into India remains uncertain. However, modern human remains dating back to the late Pleistocene (55,000–25,000 years before present) have been found, and by the middle Paleolithic period (50,000–20,000 years before present), humans appear to have spread to many parts of India. A recent

anthropological discovery provided molecular genetic evidence that a major population expansion of modern humans took place within India.

India is a land of enormous genetic, cultural, and linguistic diversity. With the exception of Africa, India harbors more genetic diversity than comparable global regions. It is generally accepted that the tribal people, who contribute 8.08% of the total population, are the original inhabitants of India. There are an estimated 461 tribal communities in India, who speak about 750 dialects. Contemporary nontribal populations of India tend to belong to overall Hindu religious fold and/or are hierarchically arranged in *Varna-Caste* organizations. The nontribals predominantly speak languages that belong to the Indo-Aryan or Dravidian families. These two linguistic groups have been the major contributors to the development of Indian culture and society. The extensive sharing of

one or two Haplotypes across population groups within India, irrespective of their geographical location, linguistic affinity, or social proximity, reveals a fundamental unity of mitochondrial DNA (mtDNA) lineages in India, despite the extensive cultural and linguistic diversity. Since mtDNA is maternally inherited, it is believed that there was a relatively small number of female lineages in India.

Evolution implies change along a definite line, and also a certain continuity throughout the change. Evolution of society and its cultural ideology and traditions requires profound social, economical, and ideological changes. As a matter of fact, a transformation of the cultural pattern in India became inevitable by virtue of the new economic organization, ideology, and administrative system the British introduced. Capitalism in the economic field, liberalism in ideological domain, and the principle of equality in the social and political systems helped change Indian society. Education, particularly education for women, brought a tremendous change in Hindu marriage and in family ideals and practices. The Industrial Revolution, which had begun before the arrival of British in India but was accelerated by them, brought industrial cities into existence and encouraged the flow of the rural population to these cities. Slowly, city life contributed to the evolution of new mode of family life, which was found to be inconsistent with the old Hindu cultural patterns.

Social changes in Indian society have also been brought on by the processes of Sanskritization and Westernization. The term *Sanskritization*, as first used by M. N. Srinivas, describes the process of cultural and social mobility in the traditional social structure of India—that is, during the periods of relative closure of the Hindu social system. It is an endogamous source of social change. Evolution in Indian society has also happened due to *Westernization*, which can be defined as the changes brought about in Indian society and culture as a result of about 200 years of British rule, the term subsuming the changes occurring at different levels—technology, institutions, ideology, and values. Emphasis on humanitarianism and rationalism is a part of Westernization, which led to a series of institutional and social reforms in India.

INDIA, PHILOSOPHIES OF

The content of Indian philosophy signifies the unbroken philosophical lineage beginning with the Rig Veda (ca. 2000 BCE), flagging one of the oldest continuing philosophical traditions in the history of global culture. This entry summarizes the basic orientations of some of the textual and conceptual regions selected from this vast philosophical history, paying special attention, whenever appropriate, to the anthropological trope of the human person.

The Vedas

The four Vedas, composed by anonymous poets (*rishis*, or seers) in the context of an oral tradition in the classical Indic language of Sanskrit, collectively constitute the *ur* texts of Indian civilization in general and Indian philosophical and religious traditions in *particular*. The four Vedas are called the Rig Veda, the Atharva Veda, the Sāma Veda, and the Yajur Veda. The Rig Veda is relatively more important for the later development of the Indian philosophical traditions. The Rig Vedic text, expressed in the form of hymns to the gods, largely voices a polytheistic tradition, where the gods signify the deification of natural elements. Within this universe of hymnal offerings, attesting to the multiple conceptual weavings implicit in the text, a significant philosophical shift can be located between the two sorts of theism: polytheism and kathanotheism, where the former assumes ontological equality between the various gods, whereas the latter, working

within a general polytheism, attributes ontological superiority to the particular god to whom a given hymn is being devoted. Going beyond the theistic framework altogether, nested in a famous series of questions, the famous *Nāsadīya* hymn (Hymn to Creation), made the startling claim that the Gods came after the creation of the world, thus robbing theism of its ontological status. Instead of giving a response to the question of how creation arose, the hymn offers a series of questions, professing ignorance regarding the question of cosmic origin. Even the gods do not have an answer to the ultimate ontological question because they themselves were born after creation. In this way, in the narrative of this pivotal hymn, the gods lose their earlier metaphysical status. It is clear that this particular hymn is keen on dismantling Vedic polytheism, making possible for the philosophical redescription of Ultimate Reality. The nontheistic and theistic articulations of ultimate metaphysical reality by the *Upanishads* and the *Bhagavad Gita*, respectively, provided such redescriptions.

The Upanishads

The Upanishads proposed a nontheistic formulation of the nature of the metaphysical substratum of reality. In the Upanishadic posture, the metaphysical structures of the human person along with the nature of objective world reality were fundamentally thematized. This formulation proceeded to provide one of the most important hermeneutic arcs under which much of the later developments in Indian philosophy would unfold. The Upanishads, collectively naming multiple texts, had as one of its central aim the postulation and elaboration of the concepts of *Brahman* and *Ātman*. The former points to an underlying metaphysical substance that, unpresentable to everyday cognition, provides the foundation of world presentation to experience. The latter is the underlying reality that allows for the ontological constitution of the empirical self. In other words, in the Upanishadic worldview, an underlying metaphysical substance anchors both the subjective and the objective orders of phenomenal experience. These notions, though transcendent to phenomenally conceived subject and object, categorically do not have any theistic resonance and thus cannot be conflated with the idea of a personal theistic God sustaining the empirical order. Indeed, for the *Upanishads*, *Brahman*, the underlying metaphysical substance of the world, is nongendered

and cannot be conceived as being invested with a personality. Furthermore, in defining *Brahman* and *Ātman* negatively as *Neti Neti* (not this, not that), the *Upanishads* summon the notion of ineffability by positing that Ultimate Reality escapes the significations of language. The *Upanishads* also consider the relationship that can possibly obtain between Ultimate Reality construed objectively (*Brahman*) and subjectively (*Ātman*). In the famous formulation “*tattva-masi*” (“thou art that”), the nondualist thesis is suggested whereby in the final analysis, the distinction between the subject and the object dissolves at the transempirical, metaphysical level. The issue concerning the relation between these two orders of reality attains central significance in the later philosophical developments of *Vedānta*, one of the schools of classical Indian philosophy.

The ideas of the *Upanishads* service a philosophical anthropology that structures the human person in a counter-Cartesian fashion. In a positive characterization of *Brahman*, the *Upanishads* claim that Ultimate Reality is *saccidanada*, meaning *sat+cit+ananda*: truth, consciousness, joy. However, given that *Brahman* makes possible the world cognition, and further given that *I am Brahman* (*Aham Brahṁāsmi*) in the final description of reality, *cit* (consciousness) in the transcendental context cannot be understood as my psychoempirical self named by my name. Thus, the human person, for the *Upanishads*, is not only the Cartesian amalgam of mind and body but includes an underlying reservoir of consciousness, *cit*, captured in the notion of *Ātman*. In other words, I am my body (*sarira*), my empirical self (*manas*), and the impersonal sustainer of my empirical being: *Ātman*, which is not implicated by my (proper) name, but makes it possible nonetheless. In the context of contemporary philosophy of mind, the *Upanishads* is perhaps suggesting that a nonmaterial conception of consciousness (*Ātman*) remains even if a reduction of mental states to brain states is effected on the argumentative grounds of materialism.

Bhagavad Gītā

The *Gītā* articulates Ultimate Reality in theistic terms. The text of this classic philosophical/religious text comprises a small portion of the massive epic of Sanskrit literature, the *Mahābhārata*. Within the narrative structure of the epic, the *Gītā* records a conversation between Arjuna, who is about to fight a war against the army of his cousins, and Krishna, his

charioteer. In the course of this conversation, Krishna reveals himself as an incarnation of the absolute theistic reality, Vishnu. Krishna, then, is the name of God packed within a theology of incarnation. Thus, the *Gītā*, through the figure of Krishna, by providing a theistic ontology, gives a counter-Upanishadic account of the absence marked out by the *Nasādiya* hymn of the Rig Veda.

The quick review of the three early textual horizons allows one to see that from the very beginning, Indian civilization in general and philosophical thinking in particular exhibited a remarkable flexibility couched in a welcoming attitude toward plurality. The accent can be placed on this trope of plurality precisely because the early religious thrust of philosophical thought did not reduce Ultimate Reality to a singularity, attesting to a deeply motivated internal differentiation to the philosophical-religious tradition of India. It may be suggested that this valorization of plurality is based on an anthropological insight concerning the structure of the human person. The classical tradition provides a psychology of religious motivation that can be seen in the famous

Source: © iStockphoto/Heidi Priesnitz.

doctrine of the four yogas: *karma yoga*, *jnāna yoga*, *bhakti yoga*, and *raja yoga*. This doctrine recognizes that a given human being is a token of a certain psychological type. Thus, the doctrine of the yogas maintains that there are different ways in which one can achieve religious fulfillment. *Bhakti yoga* is the way of devotion, which requires a metaphysic of theism because prayer cannot be directed toward an impersonal absolute (*Brahman*). Alternatively, the *Upanishads*, eschewing a theistic orientation, finds its psychological counterpart in the way of knowledge (*jnāna*) that ultimately values the direct experience of *Brahman*. Ranging over all its dimensions, concern for plurality shapes much of the philosophical traditions of Indian civilization.

While the *Vedas*, the *Upanishads*, and the *Gītā* provide the hermeneutic horizon for classical Indian philosophy, argumentative thinking is organized via the category of philosophical schools textured by their own histories and critical encounters. These schools are usually divided into two groups: the orthodox and the heterodox. The schools of the former type develop their views against the hermeneutic background of the *Vedic-Upanishadic* tradition, whereas the schools of the latter type begin only upon the critical rejection of the same textual history. The orthodox schools are Nyāya, Vaiśeṣika, Sāṃkhya, Yoga, Pūrva Mīmāṃsā, and Vedānta. The unorthodox schools are Cārvāka, Jainism, and Buddhism. These schools together traverse an astonishingly wide range of metaphysical and epistemological issues, such as causality, inference, perception, cognition, and truth, constituting a rich and powerful philosophical history. It is beyond the scope of this article to treat all these schools in detail. Accordingly, I will provide accounts of the schools of Vedānta, Jainism, and Buddhism as representatives of the classical tradition.

Vedānta

Vedānta ranges over three related schools: *Advaita Vedānta* (nondualist Vedānta), *Vīśiṣṭādvaita Vedānta* (qualified nondualist Vedānta), and *Dvaita Vedānta* (dualist Vedānta), each giving a different formulation of the relation between *Brahman* and *Ātman*, the key *Upanishadic* concepts. We shall discuss each in turn.

Advaita

The most influential thinker in the Advaita tradition was Sankara, who lived in the 8th century CE.

In discussing *Advaita*, we will exclusively summon the philosophy of Sankara because in him, the presentation of *Vedāntic* nondualism reached the highest level of philosophical sophistication.

Sankara adopts a philosophical methodology that uses a phenomenological strategy to establish ontological claims. He argues that the intentional content of consciousness continually undergoes corrections as it confronts newer experience. The content of the corrected experience has a higher ontological value. With this preliminary suggestion, Sankara proceeds to claim that consciousness is capable of types of experience that hook up to types of objects. Thus, the object of a nonveridical experience of, say, a mirage is corrected by the veridical experience of sand, leading to the conclusion that the objects of veridical experience has a higher ontological value than the objects of nonveridical experience. Similarly, the theoretical experience informed by subatomic physics that the table in front of me is mostly empty defeats the perceptual experience of the table as solid, leading to the point that theoretical objects have higher ontological value than perceptual objects. Through this phenomenological method, Sankara establishes an ontological hierarchy connecting types of experience with types of objects proceeding to the summit, which signifies the uncorrectable ground of all corrections. For Sankara, this realm of consciousness is nondual precisely because any type of consciousness that in principle is correctible must admit duality between subject and object and the plurality of objects. In *Upanishadic* language, this horizon of experience can be described in terms of the identity between *Brahman* and *Ātman*. In such a metaphysical scheme, the phenomenal world (*Māyā*), in which our phenomenal selves with their psychological states are embedded, is not unreal, but becomes so from the perspective of a higher-order experience, just as the table as solid becomes problematized only when a theoretical description of the table is admitted. For Sankara, then, reminiscent of Kant, the human person has an empirical and a transcendental dimension; but in the *Advaita* worldview, pace Kant, the transcendental self can be experienced in a transformative and liberating experience, couched in an eternal monistic identity that ultimately corrects the world-cognition. Sankara's philosophy also captures the "negative metaphysics" implied by the *Upanishads*, because his account entails that Brahman is devoid of properties and is thus beyond linguistic description;

such a view pushes the concept of Ultimate Reality into the region of absolute ineffability, experienceable but not describable.

Viūistadvaitā

The most significant thinker in the *Viūistādvaita* tradition is Ramanuja, who lived in the 11th century CE. Ramanuja provided an alternative account of the Brahman-Atman relation by arguing for a position that embraced a qualified view of the absolute but on nondualist grounds. Indeed, the name *Viūistādvaita* (*viūista+advaita*) means qualified nondualism. Ramanuja, appealing to a theory of meaning, endorsed the metaphysical thesis that properties attaching to a substance leads to an indefinite regression, because the substance in turn can become a property of another substance. To take an example: Consider the phrase "the strongly built athlete." Here, "strongly" qualifies the nature of a physique, and in turn "strongly built" qualifies an athlete, which, in turn refers to a person, and so on. Ramanuja's point is that given that properties have to inhere in a substance, all qualifications ultimately refer to an ultimate substance, which in *Upanishadic* terminology is *Brahman*. For Ramanuja, the system of difference that is the world is a real qualification of *Brahman*. While Sankara rejects the ultimate significance of the correctible realm of difference, Ramanuja endorses the position that *Brahman*, by including difference as its qualities, allows the objects of world cognition to be ontologically final. Such a position remains nondual precisely because the property is metaphysically linked to the substance. Ramanuja's position, contra Sankara, may be aligned to theism, because bearing qualities, *Brahman* appears as an object of devotion and worship. Thus, Ramanuja develops a nondual but theistic hermeneutic of the *Upanishads*, which is perhaps nearer to the metaphysical spirit of the *Gītā*. For Ramanuja, a nondual experience would be phenomenologically unintelligible; the liberating experience (*moksha*) for him is equally transformative, but duality is preserved: Brahman appears in the ultimate cognition as an intentional object of consciousness.

Dvaita

The most important *Dvaita* (dualist) philosopher is Madhva, who lived in the 13th century CE. Madhva adopts a position that conceives of Brahman as the monotheistic God creating a world, which is a system of differences. As part of his thesis concerning duality

and difference, Madhva proposes five types of fundamental differences: difference between *Brahman* and matter, *Brahman* and *Atman*, *Atman* and matter, one *Atman* from another, and one material thing from another. To know something is to recognize it as being different from something else; knowing implies the disclosure of difference in reality. Furthermore, *Atman* and material things depend on *Brahman*, the sole independent substance. Conceptual patterns in Madhva's dualist philosophy are perfectly consonant with the classical monotheistic conception of Ultimate Reality.

Buddhism

Buddhism is a religious and philosophical system founded in India by Siddhartha (called Buddha after Enlightenment), who was born in 560 BCE. The Buddhist philosophical tradition, rejecting the hermeneutic arc of the *Vedic* tradition, is an unorthodox system in the taxonomy of classical Indian philosophy. The fundamental tenor of Buddhism derives from the first sermon of the Buddha that enunciated the Four Noble Truths: suffering (*dukkha*) is the universal condition of existence; suffering originates in desire; cessation of suffering results from the overcoming of desire; to overcome suffering, one must follow the eightfold path: right understanding, right thoughts, right speech, right action, right livelihood, right effort, right mindfulness, and right concentration. The qualifier "right" in each instance, reminiscent of Aristotle, points to a middle path driven between two extremes. The teaching of the Buddha privileged the human dimension of suffering and was less concerned with developing absolute metaphysical claims as per the *Upanishadic* horizon, which is a tendency that informs the tradition's agnosticism. Indeed, the antiabsolutist stance can be found in two cardinal doctrines of Buddhism: the doctrine of change and the doctrine of *no self*. Echoing the contesting positions of Parmenides and Heraclitus from the pre-Socratic Greek tradition, the former rejects the substance metaphysics of the *Upanishads* and claims that the fundamental aspect of reality is flux; the latter extends the doctrine to an account of the self by proposing, like Hume, that the concept of an abiding self is a fiction, thus rejecting the *Upanishad's* substance-based view of *Ātman*.

The rejection of metaphysical absolutism was given a grand philosophical defense by the Indian Buddhist philosopher, Nagarjuna (2nd century CE), arguably

the most influential Buddhist philosopher in history and the main spokesman for the *Mādhyamika* system. Despite the Buddha's reticence toward metaphysics, speculative philosophy indeed developed with great power in early Buddhism in a genre of philosophical literature called *Abhidharma*. Targeting particular extant positions including positions plotted out in the *Abhidharmic* literature, Nagarjuna aimed to show that in the final analysis, all metaphysical postures are unstable. Using a brilliantly conceived dialectical strategy, he used philosophy against itself to reach the metaphilosophical position that philosophical rationality cannot yield absolute and independent positions. He shows, for instance, that the notion of causation understood in terms of the cause–effect relation of identity, difference, both, or neither all lead to contradiction when each is considered exclusively. This does not mean that causation is denied, but rather the point is that it, like all other categories, originates through a pattern of ontological dependencies. Such a thesis fiercely rejects substantialist thinking that ontologically privileges an independent ground of existence such as *Vedāntic Brahman* or the Cartesian God. This nonabsolute and interdependent nature of phenomena is termed *ūṇyatā*, or emptiness, in the *Mādhyamika* tradition. Chandrakīrti nicely summarizes the doctrine in his commentary on Arya Deva's *Catuhśatakam*, when he states that dependently originating entities cannot have independent ontological status, and since all entities arise dependently, selfhood cannot have independent existence. The nonabsolute nature of things is their *ūṇyatā*. Nagarjuna's main book, *Mūlamadhyamakakārikā*, contains apart from causality, similar dialectical analysis of a parcel of key philosophical concepts, such as time, becoming, action, and self. The text also brings under dialectical scrutiny specifically Buddhist notions such as nirvana, the Four Noble Truths, and suffering. Nagarjuna's philosophy can be seen as a vast hermeneutic gesture toward an understanding of Buddha's silence directed at metaphysics. Such a gesture was influential in the development of other philosophical traditions in Buddhism that privileged practice over theory, such as *Ch'an* in China and Zen in Japan.

Jainism

Like Buddhism, Jainism is a religious and philosophical tradition belonging to the class of unorthodox philosophical systems. As a religion, Jainism rejects

the idea that a single person founded it, because the teachings are considered to be eternal; rather, the ideas of the religion are traced to a series of *thirthankaras* who are repositories and transmitters of religious truths. Mahavira, being the latest in the series, is usually considered to be the founder of the religion.

Two doctrines of Jainism may be considered here: the doctrine of epistemic perspectivism and the doctrine of nonviolence (*ahimsā*). The notion of epistemic perspectivism is a purely philosophical doctrine but interestingly enough emerges in the context of a religious account of the human condition. Jainism, a religion that rejects the theistic conception of God, teaches that the highest salvific state yields omniscience. Motivated by this view of salvation, Jainism develops its account of epistemic perspectivism to theorize the scope and limits of human knowledge. The account is motivated by the observation that an object can present itself to consciousness in a countless number of ways. Thus, the perspective that conditions the appearance of the object to consciousness colors any judgment we make about an object. Similarly, the truth of views, theoretical or otherwise, for the Jains, is relative to conceptual frameworks and cannot achieve absolute epistemic privilege. The Jains argue that this position has a normative resonance in its implication that divergent views should be tolerated because no single theoretical position can achieve totality.

The ethical doctrine of nonviolence, though originating earlier, is given a central role in the Jain system. Making a distinction between living substance (*jiva*) and nonliving matter (*ajiva*), the Jains argue that all forms of *jiva* have moral standing. Living beings are classified in a hierarchical order ranging from the human person to microbial forms, inclusive of plant life. Every effort ought to be made in Jain ethics to avoid harming living creatures. The recent efforts in arguing for the moral standing of nonhuman animals and the environment were anticipated by the Jain teachings. The notion of *Ahimsā* influenced the political philosophy and activism of Mohandas Gandhi and through him had a bearing on many nonviolent political and civic agendas across the world.

Some Modern Considerations

A distinctive social and political turn in Indian philosophical thinking can be detected during the 19th and early 20th century. Postindependent Indian

philosophy (contemporary) connects with the classical tradition in interesting ways. We examine each in turn.

The Decolonizing Period

The great thinkers of the decolonizing period were not philosophers in the narrow academic sense, but they developed political and social positions that have great philosophical resonance. This period roughly stretches from Rammohan Ray (1772–1833) to Mahatma Gandhi (1869–1948) and includes, among others, seminal figures such as Ramakrishna (1836–1886), Swami Vivekananda (1863–1902), Rabindranath Tagore (1861–1941), and Sri Aurobindo (1872–1950). These figures were responsible for theorizing a nationalism that did not descend into a narrow chauvinism. Indeed, a strand of thinking, inaugurated by Rammohan Ray, argued that decolonizing nationalism can pay heed to the normative tropes of cultural tolerance and pluralism. The charting of a nationalism that is rendered consistent with a globally scoped pluralism and replete with cosmopolitan sympathies stands in marked contrast with other forms of reductive nationalisms extant at the time and compellingly enunciates a distinctive modernity. Tagore succinctly articulated the cosmopolitan investments of Rammohan Ray, remarkable as they were for its time, when he wrote in an article titled “Way to Unity” that Ray’s great contribution lay in forcefully arguing that truth can never be foreign. Material production can be limited to the producing country but not knowledge, or ideas, or immortal forms of art. Indeed, a scholar with a great global range including the Sanskritic, Islamic, and the Western civilizational traditions, Ray was one of the earliest cosmopolitan thinkers of the modern world.

Tagore, whose grandfather Dwarkanath Tagore was a close friend of Ray and whose father Debendranath Tagore was one of Ray’s followers, was the great inheritor of Rammohan’s pluralist sensibilities. Indeed, in Tagore, a deep internationalist in the words of Isaiah Berlin, the cosmopolitan sympathies textured every nook of his social thinking, ranging from politics to education. In Santiniketan, Tagore founded a university, Visva-Bharati, founded on two cardinal principles: a child’s education must be able to disclose the continuity between the human and the environmental; and education must range over the cultures of the world. For Tagore, only such a holistic and plural educational experience can actualize the full

potential of the human person and in the final analysis create persons with global sympathies required for cultural empathy. For Tagore, the global is not reduced to a facile recognition of alterity, but is organically linked to cultural inheritance. Tagore's sustained presentation of the idea that the cosmopolitan and the plural need not reduce to incommensurate fragments shorn of tradition makes him, as Martha Nussbaum has noted, particularly relevant to the discourse of cosmopolitanism. We can add further that such a discourse needs to be driven between nostalgic nationalisms that valorize the singular and postmodern fragmentation that can arrive at the plural only through an overdetermination of the fragment.

Sri Aurobindo is another nationalist philosopher from the decolonizing period who shaped the cosmopolitan virtues of Indian nationalism. He was also a metaphysician who gave an evolutionary account of the notion of Brahman. Aurobindo developed a speculative system in which matter is understood in terms of the "involution" of Brahman, which then proceeds through the evolutionary process to summon a state of divinized humanity. In his speculative thinking, Aurobindo attempted to synthesize evolutionary ideas with *Vedāntic* conception of the Absolute. As a political and social thinker, consistent with the evolutionary thrust of his metaphysics, Aurobindo attempted to theorize the future in terms of a cosmopolitan account of unity when he claimed that nationalism will yield to a global consciousness that will not be merely an outward gesture, but will have a deep and abiding spiritual dimension.

Significantly, the respect for the plural was championed in the context of religious multiplicity. Ramakrishna famously maintained that different religions are different paths to the same goal, and his disciple Vivekananda preached this philosophy of religious pluralism in international forums, most notably at the Parliament of Religions in Chicago (1893).

The respect for plurality animated the nationalism of Mahatma Gandhi. Indeed, the very concept of *ahimsa*, or nonviolence, on which Gandhi based his political movement is premised on such a respect. The ethical imperative of *ahimsa*, in the Gandhian scheme, commands that the same rule be applied to the wrongdoer who is an enemy as to the wrongdoer who is one's father or son. *Ahimsa* as politics when consistently applied translates into a nationalism that

is respectful toward alterity and plurality. Gandhi extended this respect to the areas of feminism and animal rights.

In contemporary European philosophy, postmodern thinking critiques a posture of modernity originating in the Enlightenment that is taken to be hegemonic in its comportments because it rejects the plural. In the structures of the decolonizing nationalism of this period of Indian thought, we find an account of nationalism that by its cosmopolitan sympathies mounts an alternative to the European account of modernity.

The Postindependence Period

Contemporary philosophical thinking in India displays, among others, two general characteristics. First, attempts are made to provide interpretive frameworks for the classical tradition. In this sense, philosophy in India continues the tradition of philosophical creativity through the writings of commentary. Second, philosophers have concerned themselves with comparative philosophy where attempts are made to study identity and difference across philosophical traditions. Sarvepalli Radhakrishnan (1888–1975) is a founding figure of the postindependent philosophical period. Much influenced by Tagore, on whom he wrote one of his first books, Radhakrishnan learned much from the towering intellectual figures of the decolonizing period, and in turn, he influenced the development of academic philosophy in the university setting of postindependent India. Radhakrishnan also embodied the two characteristics mentioned earlier: In important works, especially in *Indian Philosophy* (2 vols.), he developed creative interpretations of the classical tradition; and in books such as *Eastern Religions and Western Thought*, he made pioneering contributions to the field that is nowadays called *comparative philosophy*. Another towering figure of this period is K. C. Bhattacharya (1875–1949), who produced a highly original philosophy weaving elements from *Vedānta* and Kant. A philosopher who has defended a radical thesis concerning the nature of the classical tradition is the still-active Daya Krishna, who famously argued that the three ideas about the classical tradition—that it is "spiritual," that it is classified by "schools," and that it (at least the orthodox schools) relies on the authority of the Vedas—are myths and should be jettisoned.

A very influential contemporary philosopher is J. N. Mohanty (1928–), who has made powerful contributions to our understanding of the classical tradition, especially in his book, *Reason and Tradition in Indian Thought*. Mohanty is also one of the great scholars of Husserlian phenomenology, which makes his comparative observations especially trenchant. The economist Amartya Sen (1933–) belongs to the community of important postindependent philosophers. Many elements of his social thinking are inspired by the cosmopolitan spirit of the decolonizing period. Other notable philosophers of this period include, among others, S. N. Dasgupta, Kalidas Bhattacharya, P. T. Raju, and T. R. V. Murti.

The Indian philosophical tradition has one of the longest-running histories in the context of global philosophy. It has generated discussion of great analytical felicity and rigor in almost all areas of philosophical discourse, ranging from metaphysics to logic. The future of the tradition is enured, as Indian philosophy continues to flourish in all its varieties. This entry has been able to offer only a small sampling of this immense tradition.

INDIA, RITUALS OF

Rituals are part of India's rich cultural heritage. Religion is one of the prime social areas in which rituals function. A *ritual* may be defined as a type of organized behavior. It acts as a conservative force, binding the members of community. Ritual is mainly of two types: one that is directly related with religious activities, the other being life stage rituals, which polish and refine the individual's attitude toward society. Here, the discussion centers round the first type, the rituals associated with major forms of worship in India.

In fact, due to a national transition and global communication and interaction, Indian society is now facing change, though there are limits to change. Certain expressions that are the products of age-old beliefs do not change, and these provide the distinctive cultural template for the people of India. These rituals act as mirrors, in which the behavior of the people is reflected.

Common Elements of Rituals Associated With Worship

There are certain elements of rituals that are common to all worship: *Mantras*, or sacred words; *Mudras*, or gesture; *Nyas*, or yogic exercise of breathing; and *Bhutsuddhi*, the purification of elements. These rituals are performed by the priest at the time of worship.

Mantra: It has been generally believed that mantra is *sakti*, sacred words that have the power to evoke deities for the welfare and protection of people. These sacred words, mostly in Sanskrit, in verse or in prose, are recited during the time of worship. They can be uttered or recited loudly or visualized mentally. These words vary according to the particular worship. They are central to the ritual traditions of India. The most sacred and common word that is uttered is "Om." It has been said that this word encapsulates the entire essence of the *Veda*.

Mudras: These are gestures that act in conjunction with the sacred words. There are varieties of gestures that the priest performs, like invocation or installation of a particular deity. In the invocation gesture, the two hands of the priest are cupped together, palms upward. The installation gesture is the reverse of the above and expresses the entry of a deity. The image of a deity, be it God or Goddess, is constructed by the

artisans of a specific caste who earn their livelihood by image making, but there is a particular ritual the Hindus believe converts the lifeless image into a powerful receptacle of divinity. This is known as *Pran Pratishtha*: The priest inducts the breadth of the deity into the image with the aid of sacred uttering. It is believed that the priest is endowed with divine power at the time of worship. In this ritual, the eyes of the deity play a very crucial and revealing role. In this consecrational ritual, the eyes are painted with a final flick of black ash. And then the image of the deity is ready for intense interactions with devotees.

Nyas: This particular action is not merely yogic excises of breathing; while performing this action, the priest meditates on the particular deity of worship.

Bhutsuddhi: This means purification of the elements of which the body is composed. There are five elements, with centers in the spinal column. The most notable is at the base of the spine, the seat of the power known as *Kundalini*, or coil in the body. In yoga, this power is roused with the utterance of the sacred word “Om.”

Besides the above, there are certain common items used in most worship. These are oil lamps, incense, camphor, sandalwood, silk clothes, flowers, fruits, and food, raw and cooked. Not only is the deity prepared for the homage, but the worshippers too have a role to play. The concept of purification pervades in any worship. People bathe and fast and wear clean and sometimes new clothes. Here, the priest is the intermediary between the common people and the deity who can perform the full service of the deity. He is well aware of the rules of worship and offerings. But even the priest must go through a series of elaborate purifications in order to perform the worship. Besides the concept of purification, the concept of the *vow* also plays an important role in this ritualistic performance. This vow is mainly intended to gain divine blessings by observing an austere ritual, particularly observing fasts. It is usually performed for personal gain. This votive ritual may be described as a rite of thanks giving to a particular deity. When someone faces crisis period, such as serious illness or accident, the person or the relative makes a vow to a particular deity. After the concerned person recovers, a votary performs a particular ritual to pay thanks to the deity.

The Cult of the Goddess

The cult of the Goddess is one of the very powerful cults, whose roots can be traced back to the Harappan

civilization. This goddess may take different forms, both benign and malevolent. As Saraswati, she is the symbol of learning and culture. As Lakshmi, the divine consort of Vishnu, she represents good fortune and wealth. As Durga or Kali, she is the highest manifestation of divine power. When she is depicted as Kali, she demands blood sacrifice to symbolize her strength as the powerful enemy of the demons. These deities are part of the world as people know it, but when the special festival of a deity is celebrated, the Goddess is treated as a guest coming from the distant land. It is generally believed that Gods and Goddesses live in the Himalayas and travel across the land through the rivers. The worship itself consists of many parts, each of which shows deep reverence toward the deity as guest.

Let us start with the rituals that are associated with Goddess Saraswati. She is the goddess of speech, to whom a great hymn of the *Rig Veda* is addressed. She is generally compared with the *logos* of the Greeks. A special ritual is observed during her worship. One who wishes to acquire knowledge starts his or her lesson in front of her image. Children's education starts with her worship.

Goddess Lakshmi represents one of the most important manifestations of female power, who it is believed brings all the worldly riches to people who worship her. Indian philosophy provides explicit sanction for the pursuit of material gain, or wealth. And this material gain or the acquisition of wealth is one of the fundamental goals of life. In Bengal, the goddess Lakshmi is represented by a certain quantity of unhusked rice kept in a basket, and on the basket over a heap of rice, a wooden pot is placed. It is smeared with vermilion and is decorated by cowrie shells. Generally, on the full-moon day, the pot is installed on a platform decorated with flowers by the oldest lady of the house. The above ritual is performed by some communities in West Bengal four times in a year in connection with sowing and reaping of the paddy. In the production of rice, India's role is praiseworthy, and rice is one of the staples of Indian diet. Goddess Lakshmi is represented as “Corn Mother,” who brings peace and prosperity in every home where she is worshipped daily.

Goddess Durga is worshipped normally once a year during autumn, in the months of September to October. There is a legend that explains the origin of Goddess Durga. It is said that she is the fearsome destroyer of evil and greater than all the male gods,

through the pooling of whose powers she came into being. The word *Durga* originates from the word *Durg*, meaning “inaccessible.” This suggests that she has all the powers to fight against the evils of the world and in this way protects her devotees. The worship of Durga consists of the rituals of *Navapatrika*, or nine plants, which reveal her association with earth and the vegetative forces of nature. There, nine plants are tied together with the vines of a flower, named *apara-jita*, meaning “undefeated.” The nine plants are the following: banana plant, kacu (an edible root plant), turmeric root plant, Jayanti (a kind of tree plant), bael plant, pomegranate fruit, asoka plant (a kind of tree twig), arum plant, and paddy, the unhusked rice. In a way, these nine plants symbolize human life and represent items that are necessary for maintenance and happiness. These plants have great significance even separately, and they form the basic ingredients of cooking. All these plants are fit representations of the Goddess; it is through creation that divinity is comprehended.

Besides these nine plants, the other indispensable items of worship are water, flowers, and the *ghat*, a vessel that plays an important role. The vessel is made of clay, and sometimes copper vessel is also used, as copper is regarded as pure. A diagram is drawn on the ground. Then, a swastika sign (symbolizing good fortune) is painted on the vessel using vermilion. After that, the vessel filled with water is placed on said diagram. The open mouth of the vessel is covered with a bunch of five mango leaves and a coconut smeared with vermilion, and a small towel is placed on it. The coconut must come with the stem, as it is regarded as a sign of fruition and creation, symbolic of the Goddess’s function. Here, the vessel is sacred as it symbolizes the abode of Goddess. Then, with the chanting of “Om,” the worship begins. This mystical syllable “Om” represents the essence of the cosmos. By repeating it at the beginning of worship, the devotee moves into a state of readiness for contact with the supernatural. In any worship, man and nature are identified. It is being upheld that the human body is made by five elements of earth, water, fire, wind, and sky. The

skin is composed of earth; the tongue is made up of water; fire is represented in the eyes; wind is equivalent to the nose; and sky corresponds to the ears. As these elements are mixed together in symbolic rites, the priest is filled with divine power. Most of the rituals indicate the lifestyle of the local people and their ways of living. There is a custom of submerging the image of deities in water after the worship ceremony. This custom, which is part of the ritual process, is found throughout India. This ritual process has both a theoretical and practical aspect. The Indians, particularly the Hindus, believe that the invisible is reached through the visible; an image is only an instrument to reach the supreme. The immersion ceremony signifies the impermanence of the material things, and moreover, it has the practical effect of keeping artisans who build these images employed every year.

Though Goddess Durga is worshipped once in a year, Goddess Kali is normally worshipped only in permanent temples. In Bengal, the worship of Kali is a regular event. But Kali, like Durga, is also worshipped in Bengal once a year, in a clay image made for this occasion only. Her worship falls on the night of the new moon, following the worship of Durga. Kali is the “Dark Goddess,” a term that originally derives from the word *Kala*, meaning time, and she has been always identified with death and is regarded as the destroyer of evils.

Part of the bas-relief “Arjuna’s Penance” at Mahablipuram, a World Heritage Site south of Chennai, India, on the Bay of Bengal. The rock carvings date back to the 7th century A.D. and are among the earliest known examples of Dravidian architecture.

Like the other festivals, this worship has its own ritualistic performances, which can be broadly divided into two categories, daily and occasional performances. Hibiscus flowers are offered to Goddess Kali. This flower is considered to be the favorite present to Kali because it is the color of blood. Besides flowers, there are rice offerings, *arati*, waving the oil lamps in a rhythmic fashion in front of the deity, and after an offering of a light meal, the sleeping ceremony follows at night. Among the occasional performances, the ritual of sacrifice is there. But this is not a necessary item, and it depends on the initiative of the pilgrims. The services to the Goddess are part of a reciprocal relationship between human and divine.

In other parts of India, this festival is known as Diwali or Depavali, the festival of lighting the lamps. The main ritual of this festival is to light candles or earthen oil lamps. Due to globalization, many things have changed. But the ritual to light earthen oil lamps with cotton wicks, particularly in front of the deity, still persists. Earthen oil lamps are considered as purest and best. From the sociological standpoint, at least once in a year, these earthen lamps are produced on a massive scale, by those who earn their livelihood as potter.

In India, Diwali has a special importance among the Jains, the followers of Lord Mahavira. It has been a ritual among the Jains to observe the lamp festival every year on the very day of Lord Mahavira's *nirvana*, his passing away from this worldly life. In fact, since the discovery of fire, its influence is keenly felt in all spheres of life, including the traditional rituals. The flame of lamp is considered in India as the symbol of rebirth, and this is the reason why its ritual use is found in everything connected with death. The mystery of plant life is inextricably associated with the primitive conception of rebirth, and as Dewali is a ritual of death and rebirth, it is likely that it would maintain a relation with plant life. In some parts of Bengal, there is still a ritual of eating 14 kinds of vegetables on the day before the commencement of the Diwali festival. And these vegetables symbolize the herald of new life that follows inevitably after any destruction.

The Cult of the God

Like the cult of the Goddess, there is also cult of the God, and God Shiva plays a very dominant role. Shiva is described as the lord of the universe, seated on the bull, the giver of boons, three-eyed, his body

besmeared with ashes, a small drum and trident in his hands, the head marked by the moon, and a serpent on his neck. Besides this image, God Shiva has another form that is very popular throughout India. In the Shiva shrines, it can be observed as devotees carry pots of holy Ganges water, which they pour upon the phallic form of the God, with sandalwood paste, incense, and leaves of bael (*Aegle marmelos*). The bael leaf, with its trifoliate design suggestive of Shiva's trident, is considered to be an essential ritual for the worship of the God Shiva. Solitary solemn prayer is one of the important rituals of the whole process.

Besides Lord Shiva, Ganapati is an important deity, and his image is represented with a human body and an elephant's head. Ganapati is the God of Wisdom, the deity who can remove all obstacles and grant success in our endeavors. His name is invoked before beginning any new venture. Ganapati is very popular all over India, but a special public celebration occurs in the state of Mumbai in the month of August to September, after the end of monsoon. The rituals that are associated with this festival vary, but the general rituals are almost same everywhere and include prayers, lamplighting, offerings of jaggery (from palm sap), grated coconut, cardamom seeds, and dried fruits. There is a social significance behind this festival. During the festival days, people can mix together, forgetting their internal differences, and cultural awareness develops among the younger generations. After the festival, the immersion ceremony occurs, which is very colorful in Mumbai. On this day, the image is installed on a cart, and people in large numbers join the procession and follow along, going down the streets toward the seashore, striking cymbals and gongs, everyone shouting, "Father Ganapati, come again! Auspicious one, come again." Sometimes, the icon is carried in a palanquin. Chanting of hymns is one of the rituals, while people watching from the roadside shower colored powder on them.

This showering of colored powder resembles another major festival of India, which is known as *Holi*. Lord Krishna is the incarnation of Vishnu, the Vedic God, in a human form. Krishna as an incarnation is God himself, thus showing a close similarity to Jesus, of Christian theology. This festival is celebrated on the full-moon day of spring, while that of Diwali is on the new-moon night at the advent of winter. Winter and spring symbolize, respectively, the death and revival of the year, and the annual cycle of birth

and death in nature. The most remarkable ritual of the festival of Holi is the use of the red powder, smeared on the bodies of the friends and relatives. Other colors are also used. Even strangers are treated as friends on this day, and sweets are offered to all, irrespective of caste and creed. Sometimes, red powder is mixed in water, and then this water is sprinkled on people. It is a festival of enjoyment and fun. In the 21st century, when India is at the crossroads of technological revolution, this age-old ritual is still maintained in some form or other. The red powder that symbolizes the color of blood signifies also the life-giving power. In spring, the growth of new leaves on the trees signifies the revival of new lives in nature, and the spring festival celebrates this renewal.

Another rejuvenated ritual can be observed in the worship of Lord Jagannath, from whom the English word *juggernaut* originates. This famous chariot festival known locally as Ratha-Yatra, at Puri, in Orissa, a state of India, stands out amidst all the observance of ritualistic performances. From the image making to other associated rituals, this festival deserves special mention. The festival starts a fortnight before the procession of the chariots, on the full-moon day of the month of May to June with the bathing rituals. This ritual ceremony lasts only one day and is followed by the period of illness of the deities. And after that, the chariot journey begins, from the main temple toward another one named *Gundicha* temple. During the months of June and July, the chariot festival takes place. This is the time of rejuvenating the deities and thereby renewing the bonds between the people and the land. As it has been observed, the images of the deities are normally made of clay, but the deities of Jagannath temple are made of wood. And it is a custom to replace the old wooden images after every 12 years.

On the morning of the bathing festival, the ritual functionaries fetch water from the nearby storeroom of the temple. This water is placed 108 pots, and the ritual functionaries pour water on the wooden deities. After the bath, one temple servant who is the representative of the king performs a ritual called "sweeping." With a gold-handled broom, the whole area is swept, and then sandalwood powder is sprinkled. After that, huge elephant's head masks are fastened on the images. Then the deities are offered sixteenfold offerings. The temple cooks bring the food in earthen pots.

After the bathing day, the period of illness of the deities follows. During this "dark fortnight," there is

no beating of gongs or conch shells, and the temple is silent and deserted. At that time, herbal medicine and raw food are offered to the deities. On the 13th day of the dark fortnight, the paintings begin on the images, which were faded due to bathing ritual. On the dawn of the 15th day, the new-moon day, the period of the illness is over, and the gate of the temple is opened for the public. A welcoming ritual is observed in their renewed state. In the second day of the "bright fortnight," the chariot festival begins. There are three chariots covered with bright colored cloths. The color of the cloths vary according to the deities. Lord Jagannath's chariot is covered with yellow and red; that of Balabhadra, his elder brother, with green and red; and Subhadra, their younger sister, with red and black. Besides these deities, brightly colored wooden sculptures of side deities are made for this occasion to adorn the chariots. The images are decorated with flowers and other accessories. Then, the deities are placed on the chariots.

Before the procession starts, an important ritual has to be performed by the king. Though the kingdom was gone, the ritual is still there, and it is observed every year by the king's descendents. The king used to sweep the main road from where the procession started with a gold-handled broom. This is symbolic, to show all are equal. After this ritual, a pair of wooden horses are attached to the front of each chariot. Then, the ropes are fastened, and after the signal, the crowd starts to pull the chariots toward the Gundicha temple, almost 2 miles away from the main temple. In that temple also, elaborate rituals follow including bathing. On the 10th day of the bright fortnight of this same month, the return journey of the deities occurs. The same rituals are repeated. After their return, the deities are placed in their old positions, and daily worship takes place as usual.

Here, in the observance of the above rituals, the deities are treated in an anthropomorphic fashion. The desires of the people are reflected in the decoration of the deities. People want to see the deities as almighty, having all the good qualities, and achieving perfection. As humans are treated with care, so the deities also receive special attention in the period of illness that happens after a long course of bathing. As in the case of humans, so in the case of deities, medicines are applied for cure. After recovering from sickness, the deities are ready to appear among the public with much rejuvenated vigor. The sweeping ritual by the king indicates that no work is inferior.

Cleaning and sweeping are parts of our lives, and as humans, we are all equal. This chariot festival brings the aristocrats and the common men together.

The Personification of River

The rivers, as well as the deities, are worshipped with elaborate rituals. In different states of India, particularly in Benaras and Hardwar, this tradition of worshipping the river is very prominent. The river is treated as a *Devi*, or Goddess. In Hardwar, a state of North India, located at the base of the Himalayan foothills, where the celestial river Ganges enters the plains, this ritual of worshipping deserves special mention. Amidst the hustle and bustle of daily living, this city witnesses every evening a fascinating event that differentiates the city from other parts of India. As the day wanes and slowly dusk approaches, a typical phenomenon happens near the famed bathing bank, which is locally known as *har-ki-pauri*, meaning “the Lord’s Stairs.” Innumerable lighted oil lamps can be seen in the hands of the priests coming out from the nearby temples toward the Lord’s Stairs. While standing on the stairs at twilight, chanting prayers, the priests wave the lighted oil lamps in a rhythmic rotary motion known as *Ganga Arati*, an offering to *Devi Ganga*, the personification of the river. Thousands of people sit or stand near the stairs and watch this ritual, spellbound, as part of the whole ceremony. After this, there is a ritual of leaf cup offerings of flowers with burning oil wicks; people place them in the water, and they float downstream. This ritual is observed as part of wish fulfillment, as if the flowers are people’s high hopes, sailing along the water. If the leaf cups of flowers with the twinkling oil wicks float straight downstream without sinking, then it is assumed that one’s secret desire will be fulfilled. If they sink at the very start without moving a bit, then one takes it as a bad sign.

Rituals are cultural motifs that reflect the nature of a particular society and the relations among people. Like a compass, they help one chart a course through life. India, a multireligious country, has divergent codes for life. In any religion, rituals have been and continue to be important for establishing social identities that constitute the “maps” for regulating public relations.

INDONESIA

The Southeast Asian country of Indonesia is composed of 17,508 islands (6,000 inhabited) and straddles the equator from the Indian Ocean to the Pacific Ocean. In area, it is more than three times the size of Texas. Indonesia has a hot, humid, tropical climate that is more moderate in the volcanic highlands.

The earliest inhabitants came to the Indonesian island of Java about 2 million years ago. At that time, there was a single landmass from Southeast Asia to what is today Malaysia, Sumatra, Borneo (Kalimantan), and Java. This landmass is referred to as the *Sunda shelf*. About 2 million years ago, *Homo erectus* migrated through what is today Malaysia, then Sumatra, and finally Java.

A wave of farmers came to Indonesia from northern Southeast Asia beginning about 5,000 years ago and reached western Indonesia by 3,000 years ago. This migration initiated the extinction of the original anatomically modern inhabitants of the tropical forests of Indonesia, which are the Negrito hunting-and-gathering populations. These indigenous populations are still found in the remote islands of Eastern Indonesia.

The Dutch began to colonize the islands in the early 17th century, and they were later occupied by Japan from 1942 to 1945. Indonesia declared its

independence after Japan's surrender at the end of World War II, but there were 4 years of widespread hostilities by the Dutch before the Netherlands agreed to relinquish its colony.

As of 2004, the population of Indonesia is estimated to be over 238 million people, with the bulk living on the island of Java. Indonesia has the fourth-largest population in the world. Approximately 88% of the population are Muslim, 5% Protestant, 3% Roman Catholic, 2% Hindu, and 2% Buddhist. Indonesia is composed of four major ethnic groups. The Javanese compose about 45% of the population, while 14% are Sundanese, 7.5% Madurese, 7.5% coastal Malays, and 26% other. Although several thousand languages are spoken, a modified form of Malay called "Bahasa Indonesia" is the official language. After Bahasa, Javanese is the most common language, followed by English and Dutch. At 87.9%, Indonesia has one of the highest literacy rates in the world.

Current issues of concern to Indonesians include alleviating widespread poverty, preventing terrorism, continuing the transition to popularly elected

governments after four decades of authoritarianism, implementing reforms in the banking sector, addressing charges of cronyism and corruption, holding the military and police accountable for human rights violations, and resolving armed separatist movements in Aceh and Papua.

INDUS CIVILIZATION

In the second half of the third millennium (2500–1900 BC), a civilization flourished in the northwestern sector of the Indian subcontinent. It extended from Afghanistan into portions of Baluchistan in Pakistan, to the Indus Valley and along the tributaries of the Indus River, eastward to the Himalayan foothills and Indo-Gangetic plain, and southward to the Indian states of Gujarat and western Madhya Pradesh. This cultural realm covered some 1 million square kilometers. At the time of the discovery of this advanced urban culture in the early 1920s, as revealed by surface finds of artifacts and ruins of building structures, it was labeled the "Indo-Sumerian civilization." But as explorations proceeded, it came to be known as the "Indus civilization" or "Indus Valley civilization." Some archaeologists refer to it as the "Harappan civilization," since the earliest archaeological excavations took place at the site of Harappa, on the banks of the Ravi River in 1921, under the supervision of Rai Bahadur Daya Sahni (1879–1939). Four years later, the site of Mohenjo-daro, on the Indus River, was excavated under the direction of the British archaeologist John Marshall (1876–1958). Although

some 19th-century British explorers had collected surface artifacts at Mohenjo-daro, Harappa, and other sites, it was Marshall who recognized the unique characters of this hitherto unknown unique Bronze Age civilization of South Asia. He was aware that its cultural influence had diffused to Iran, Mesopotamia, and to the Arabian Gulf, as some Indus seals and pottery had been found in these regions, but there were only vague references to the Indus Civilization in Sumarian, Iranian, and Egyptian texts. It is possible that the Mesopotamian and Gulf localities of Dilmun, Magan, and Meluhha mentioned in 2nd and 3rd millennium BC written records may have referred to important trade centers that Indus merchants reached by coastal sea routes.

As excavations progressed at Harappa and Mohenjo-daro, other Indus sites were discovered in Afghanistan, India, and the northwestern sector of the subcontinent,

including the present nation of Pakistan, which gained independence from British colonial control in 1947. Over 1,000 sites dated to the mature Indus phase are known today. Some were towns such as Chanhudaro, on the lower Indus River and Lothal in Gujarat, while other settlements were large urban centers such as Kalibangan, in Rajasthan, and Dholavira, on Kadir Island, in the Great Rann of Kutch. The socioeconomic basis for these centers included wheat and barley agriculture and pastoralism. Goats, sheep, and cattle were the predominant domesticated animals, but hunting continued to supplement food resources. Although there is regional diversity, the Indus Civilization is distinguished by a carefully regulated system of city planning. Streets are laid in a grid pattern and feature public structures and platforms, houses and court-

yards, walls, and platform structures once considered by some archaeologists to be foundations for granaries. There were water-filled baths, tanks, wells, and bathing rooms within residential compounds. Working areas for firing pottery and threshing grain are present. The construction of drains running along the streets testify to the sophisticated level of hydraulic engineering for public sanitation. However, unlike the ancient cities of Egypt, Mesopotamia, and China, the Indus people did not erect monumental structures such as temples and palaces, although gateways and platforms approach grand architectural achievements. Mud and fired bricks were the principal building materials, all made to the same size, as were graduated series of standardized stone weights and measures.

Among other distinctive cultural features were wheel-made and well-fired ceramics, often with

characteristic floral and animal designs on urns, pots, dishes, and different types of household wares. Figurines were made of bronze, stone, and terracotta. Bronze was the material for short swords, knives, axes, and spearheads, as well as for utilitarian tools, such as chisels, saws, fishhooks, and sickles. Ornaments were of gold, silver, lapis lazuli, shell, and discoid beads, often shaped from stones imported as far away as the Bay of Cambay. The Indus script carved into steatite or formed as stamps of fired clay record an unknown language that has not been deciphered. It is likely that the script with their accompanying representations of plants and animals did not function as texts, but served as markers of ownership, contracts, and accounts.

Because of the unexpected discovery of the existence of the Indus civilization, it was assumed by some early archaeologists that its origin was abrupt and without any antecedent cultural associations. But later investigations demonstrate that village farming communities and pastoral camps had been thriving in the north-western sector of the Indian subcontinent as early as 7000 BC. Archaeological evidence of herding of sheep and goats dates to around 10,000 years ago in Afghanistan. Within and along the margins of the Indus realm were a number of cultures dating from 4500 BC to 2300 BC, which are identified by cultural locality names (e.g., Togau, Kechi Beg and Hakra, Amri, Nal, Kulli, and Kot Diji). Each is distinguished

by its ceramic forms and paintings and other artifacts, including copper in some of these pre-Indus cultures, along with the implements of a village farming and pastoral way of life. The first stages or phases of the Indus civilization fall within a chronology of 2600 BC to 2500 BC. The mature phase continues for over 600 years (2500–1900 BC), to be followed by

posturban cultures identified as Jhukar, Early Pirak, Cemetery H, and other cultural entities that reveal the decline of the Indus civilization but a perpetuation of some of its material cultural elements in adjacent geographical regions.

Funerary customs of the mature Indus phase were of considerable diversity: earth burials in cemeteries with the skeletons in extended or flexed positions, secondary and fractional burials with partial skeletal remains deposited in pots and urns, cremation, and isolated interments of one or a few individuals. Preservation of skeletal and dental remains from the sites of Mohenjo-daro, Harappa, Kalibangan, Chanhudaro, Lothal, Rupar, and at some other Indus sites have allowed biological anthropologists to describe the physical features of the inhabitants of these localities and reconstruct demographic patterns of their populations. Furthermore, data concerning the health status of these earlier peoples can be ascertained by measurements and morphological observations of bones and teeth. Results of these studies by research teams from Pakistan and India and by foreign investigators (principally from the United Kingdom, United States, Germany, and Italy) show that there was a relative degree of genetic heterogeneity among the architects of the Indus civilization. Across the immense geographical regions of their cultural influence, populations had adapted to different environmental conditions as well as responded to various biological stresses imposed by local cultural traditions. In short, there is no “Indus race.” Rather, the range of biological variability observed in skeletal and dental remains confirm that they are “typically” South Asian in their ancestry and not descendants of some exotic hordes of invaders from unknown places of origin elsewhere in Asia.

The question of the ancestral identity of the peoples of the Indus domain is relevant to questions concerning the decline of their mature phase circa 1900 BC. The British archaeologist Mortimer Wheeler (1890–1976) proposed that this civilization collapsed suddenly because of an invasion of Indo-European-speaking conquerors, the Aryans of the Vedic accounts of ancient India. Vedic India marks the period of a second rise of urbanization in the subcontinent almost 1,000 years after the decline of the mature Indus phase. Wheeler sought the evidence for this in the skeletons at Mohenjo-daro, which were not recovered from formal burials, but lay scattered over different parts of the site. Today, we know that the

dating of such an invasion, if indeed one had ever occurred, was too late to coincide with the decline of the Indus civilization, and both the archaeological and biological anthropological evidence provide no support for this thesis. Better hypotheses are that there were gradual changes related to socioeconomic and ideological transformations in those cities and villages, which became less important as mercantile and manufacturing centers. It is unlikely that the Indus civilization had formed an empire or a national state, as the symbols of kingship are not present in the archaeological record. Within the broad spectrum of commercial interactions between the Indus Valley and the Mediterranean Sea and covering the lands between Central Asia and the Arabian Gulf were diverse human populations, ecological settings, and languages of which the Indus civilization was one center during the 3rd millennium BC.

New discoveries continue today with the finding of more sites and reanalyses of earlier hypotheses about the Indus peoples. American scholars active today in the archaeological sphere include Gregory L. Possehl of the University of Pennsylvania, Richard Meadow of Harvard University, Jonathan Mark Kenoyer of the University of Wisconsin, Louis Flam of Lehman College, and Rita Wright of New York University. The biological anthropology studies have been undertaken by John A. Lukacs of the University of Oregon, Nancy C. Lovell of the University of Alberta, Brian E. Hemphill of California State University at Bakersfield, and Kenneth A. A. Kennedy of Cornell University.

INFORMANTS

Native individuals who provide information to an ethnographer during fieldwork are referred to as *informants*. The term implies a procedure during ethnographic interviewing in which semistructured or informal in-depth questions are asked in a naturalistic setting, and informants answer. Recently, other terms such as *consultants* or *collaborators* have been preferred, indicating the greater participatory and equal role of these key individuals in the modern period. Since 1971, the American Anthropological Association has published guidelines that set out the ethical responsibilities anthropologists have to informants. These include avoiding harm or wrong, respecting informants' well-being, safety, dignity, and privacy, actively consulting in order to establish beneficial relationships, and protecting anonymity if that is desired. Increasingly, ethnographers submit proposals to institutional review boards, which examine research involving human subjects. Like other scientists, ethnographers then are required to obtain the informed consent of their subjects.

A trusting, reciprocal, and cooperative relationship between informants and ethnographers develops gradually throughout the fieldwork period. Since ethnographic interviewing often involves financial payments, informants benefit from their participation directly. Informants also may gain respect and prestige from working with anthropologists. They may expect friendship, favors, or gifts. As relationships change and deepen, ethnographers gain additional insight into the culture from the emic or native point of view. Eventually, informants provide cultural interpretation and analysis, not only cultural information.

Ethnographers select different kinds of informants depending on their research design and goals. If the ethnographer is seeking to write a general cultural description, a variety of informants, old and young, men and women, may be necessary. Each of these has ordinary knowledge that the ethnographer combines through a series of interviews, building them into the account of the culture. If the ethnographer is writing a description that requires expert knowledge, such as a study of shamanistic beliefs and practices, then perhaps only those who have this kind of knowledge become informants. Many ethnographers find that they develop special rapport with only one individual and that person becomes the key informant and often

the focus of a person-centered ethnography. Research projects may interest certain people more than others, and some topics may be ignored or devalued. Thus, ethnographers interested in gender and women's experiences may be disregarded by the men of a particular culture. Such circumstances may enhance the relationship between women informants and women ethnographers.

Ensuring the accuracy and validity of informant provided data is an important methodological problem in ethnographic research. In contrast to survey-based inquiries, where replicability and comparison to outside data may be possible, informant-based data are critically assessed via a different process. Ideally, increasing rapport should produce increasing accuracy, but this is not always true. Informants may lie, avoid sensitive issues, or just not know. Ethnographic research offers the possibility of repeat interviews in which information can be checked or clarified. In addition, checking data via multiple informants may indicate whether the informant is "typical" or "idiosyncratic." Ethnographers also check informants' statements against their own observations. Informants' misrepresentations or avoidances provide cultural information just as their accurate statements do.

INOKUN VILLAGE

The Ejagham civilization is one of the most ancient civilizations in the world. The Ejagham nation extends from Manyu Division in the southwest province of the Republic of Cameroon to the Cross River State in the Federal Republic of Nigeria. Long

years of contact with the outside world, especially European civilizations, have greatly tempered the Ejagham way of life. One region, however, has retained most of the ancient Ejagham cultures and traditions in nearly their pristine form. The lower Ekwe region has been described as the last true preserve of the Ejagham civilization.

“Lower Ekwe” is a term coined to describe a group of contiguous villages that have evolved into a peculiar subculture within the Ejagham nation, with a dialect *Ejagham Njemaya* (meaning “Ejagham from across the river”) that easily distinguishes them from other speakers of the Ejagham language. The villages that make up lower Ekwe include Araru, Babong, Inokun, Mbenyan, Okurikang, and Onaku. The village of Inokun is the hub of this subculture. Its history, its politics, its art forms, its institutions, and its value systems best illustrate the accomplishments and the excesses of the Ejagham civilization.

Legend

Inokun is made up of two quarters, Ntasek and Ntota, descendants of two brothers. The two quarters are separated by a small stream (*Akem-ayeb*), which flows right through the center of the village and is commonly used for bathing and laundry. No one remembers exactly where the founding brothers came from or when they settled in present-day Inokun, but legend has it that through pure grit and servile labor, they subdued the land and built the most important commerce center of their times. A tradition of hard work was implanted. The first professionals, other than medicine men, who did not live off the land were the craftsmen. Inokun became famous for its highly skilled artisans (artifacts from the 18th century remain). Marketing of their work led to the establishment of a trade route linking the lower Ekwe area to the cosmopolitan port city of Calabar, Nigeria. Valuables like pottery, sculpture, animal skin, food-stuff, domestic utensils, household implements, and musical instruments were being exported, while manufactured goods such as lamps, hunting rifles, radios, loincloth, and sewing machines were being imported in ever-increasing proportions. By the turn of the 20th century, Inokun boasted of a culture of *nouveaux riches*. They were easily identified for smoking a pipe, sporting a top hat, while riding a bicycle (locally referred to as the “iron horse”). Ejagham architecture was the principal casualty of this new

wealth. The Ejagham method of building consists of a framework of interwoven sticks padded with mud and roofed with thatches. Mud was being replaced by cement, and thatches were giving way to corrugated metal sheets locally referred to as “zinc.” Zinc quickly became a status symbol to the extent that those who could not afford both had to choose between buying a bicycle and covering their homes with zinc. The use of mud and thatches, though common today, is easily associated with poverty.

Setback

Inokun has seen its importance diminish from the days when it was host to the only school and the only native authority court in the Ekwe area. The reasons for Inokun’s dramatic reversal of fortune, from precursor of modernism to custodian of antiquated customs and traditions, cut across politics, geography, and unyielding pride. The story of Inokun, like that of most sub-Saharan people, is a story of bad government. Inokun lost much of its independence when it was incorporated into Eyumojock Subdivision, but never given access to Eyumojock, the administrative capital. The people of Inokun are required to trek for several miles through the forest to Eyumojock for basic health care needs, to register births, to attend secondary school, to make a police report, or even to buy stamps. There is a zero-police presence in Inokun, a void that is occasionally filled by vigilante justice. Women still give birth at home, attended by local midwives ill-equipped to handle certain complications. The result is a staggering loss of women during childbirth and a disconcerting ratio of stillbirths to live births. Inokun has no electricity, no pipe-borne water, no gas, no television signals, and no telephone. Houses have no plumbing, and the main source of cooking fuel is firewood.

Several efforts by the locals to create a motorable road network linking Inokun to other areas have been futile, mainly because the topography of the entire Ejagham land is very rugged. Traveling from Eyumojock to Inokun requires trekking through difficult terrain beset by a series of tortuous hills, culminating in a forbidding descent known as “Akategui.” At the foot of Akategui flows the treacherous river Akarem. There is no bridge over Akarem. The navigable downstream of Akarem is no more than 30-feet wide and 4-feet deep in the dry season. But the riverbed quickly wells up in the rainy season, acquiring a

violent current that has washed away many a traveler, never to be seen again. Some natives consider this a perennial sacrifice necessary to propitiate the gods of Akarem.

Economy

The economy of Inokun today is much like it was a couple of centuries ago, except for the arts-and-crafts industry, which has all but disappeared. The only real change is the use of money to replace cowries as the medium of exchange. The people live off the land, growing their own food and hunting wild game. Food crop farming is the mainstay of the economy. Farming techniques are rudimentary, consisting mainly of a hoe and a machete. Consequently, farm holdings are very small. Bush burning is being discouraged, but the absence of an alternative time-saving method of preparing the farmland for tilling means bush burning will remain a common practice for the foreseeable future. Animal farming is very limited, consisting mainly of a few goats, pigs, and poultry usually left to roam about and fend for themselves. Because methods of food preservation are not very advanced (mainly smoking and drying), the people are still struggling with food self-sufficiency. Cash crop farming is the main source of income. Cocoa, coffee, bush mango (*ogbono*), garri, and eru are the main exports.

The political system in Inokun is unique in its fusion of all powers—executive, legislative, as well as judicial—within the council of elders. Inokun is a monarchy. The chieftaincy is hereditary. The chief exercises power through his council of elders made up of wise men from each quarter. At the quarter level, every adult male is required to participate in the political process. The surest way to make one's opinion count is membership in the Ekpe society, the principal decision-making body. The Ekpe society is a sacred society open to all responsible adult males who can afford its initiation requirements and adhere to its policy of secretiveness. Membership in the Ekpe society is also considered the ultimate measure of manliness, and any adult male who is not a member is derided as a woman. The Ekpe society ensures discipline within its ranks through a system of hierarchy and through the imposition of stiff fines for unethical conduct by members or their dependents. However, the Ekpe society is usually regarded as a society of greed because fines are usually paid up in food and

drink consumed exclusively by the members of the Ekpe society. The female equivalent for Ekpe is the Njom-Ekpa, also a sacred society empowered to handle exclusively female issues.

Legal System

The legal system in Inokun has persisted from the distant past. Although the chief of the village is an auxiliary of the central administration and is required to report all serious crimes to his superiors, the people of Inokun always try to resolve their legal problems within themselves. There is an unspoken code among the natives that bringing one's neighbor before the courts is an unpardonable breach of communion. Disputes that cannot be resolved within the family or at the level of the quarter are brought before the chief and his council. The chief's court hears cases ranging from simple disputes to murder, and it operates under a set of traditional legal principles, which accept witchcraft as evidence. Consider the case of two young men who went on a hunting expedition in the early 1980s; one returned the following day with a confession that he had shot and killed his partner. In his defense, he said his partner had transformed himself into a baboon to lure other baboons to come within fire range. Unfortunately, the one baboon he had shot and killed turned out to be his friend. Since there was no history of animosity between the two young men, the hapless hunter was summarily acquitted. He was asked to undergo major cleansing.

Kinship

Kinship patterns in Inokun can be as simple as they can be hard to decipher. The Ejagham culture encourages closeness among its people to the extent that any two persons connected by blood are considered siblings and are expected to treat each other as such. The Ejagham words for brother, *mone-nseh* (literally, "father's child"), and sister, *mone-nyen* ("mother's child"), are applied to cousins and even second cousins. However, when the words *mone-nseh* and *mone-nyen* are used in reference to persons other than direct siblings, they are usually followed by a qualifier. For example, I would introduce my cousin thus: "Anna is my sister. Her mother is my mother's sister." Similarly, the Ejagham language does not have a single word for nephew. To introduce a nephew, you could say, "Ashu is my brother's son" or "Ashu is my

son; his father and I are brothers.” Keeping track of kinship is especially important in a culture where incest is at the top of its list of taboos. Cousins as well as second cousins cannot marry.

The extended family (*ndeb-nju*) is arguably the most important social structure within the Ejagham civilization. The extended family more than makes up for a nonexistent welfare system within the broader society. The extended family also eliminates the need for orphanages, adoption agencies, or homeless shelters. In a typical Ejagham society, there are no old-people’s homes, and there are no homeless people. Marriage in Inokun following the proper traditional pattern is a protracted and arduous affair. The suitor makes his intent known by carrying drinks to his intended in-laws. If the initial drinks are accepted in good faith, courtship is officially on. Over the next few weeks, the suitor brings presents and more drinks. Then, he can start seeing his bride-to-be. In effect, he may have relations with her. She stays with her parents until she has her first child. Right after she has her first child, she is circumcised. Then, she is kept in a special room known as a “fattening room,” away from the public. She is kept in the fattening room for 6 months, or in the case of well-to-do families, for a whole year. Here, she is not allowed to do any work, and her family is on hand to cater to her needs. At the end of her stay in the fattening room, she is given a complete makeover, and the public is allowed to see her for the first time. That same evening, a group of her husband’s age mates come to escort her to her new home, bearing her high on their shoulders amidst singing and dancing. The number of traditional marriages has recently dropped, because since the 1990s, many feminist groups have been waging a sustained campaign against female genital mutilation. Some hidebound traditionalists are still unwilling to part with the practice.

Although Inokun has had contact with Christianity for almost a century, when many natives were baptized as a courtesy to the missionaries, the people of Inokun are essentially animists. The bulk of the population is nominally Christian, a great majority of whom are Catholic. A major breakthrough in the conversion of the natives was the translation of the Bible into Ejagham in the 1990s, but the impact was undermined by the fact that most of the natives are unable to read and write.

One of the enduring beliefs is that every descendant of Inokun has a double in the form of a mudfish,

which inhabits a small pond called “Ayeb-Ikwi.” Ayeb-Ikwi is also a major source of drinking water. Expectedly, no one fishes in Ayeb-Ikwi. When a child is born to an Inokun household, the event is replicated by the birth of a mudfish in Ayeb-Ikwi; and if by any chance, a mudfish is killed in Ayeb-Ikwi, its human double dies. There is a cloven of witches from all over the Ekwe area, which meets in Inokun after dark to decide on whose home to visit. The witches are known to fly at incredible speeds. They feed on flesh and blood and leave their victims with disease. Villagers mark themselves to render their flesh unsavory or hang fetishes on their doors to ward them off.

The people of Inokun have a genuine fear of ghosts. Ghosts are so pervasive that they control nightlife and influence burial patterns. It is generally believed that in a case of accidental or untimely death, the restive spirit of the dead will hover if it is not pacified prior to laying the body to rest. In a case where there is suspicion of murder, the spirit of the dead is encouraged to return and exact vengeance. In this case, it is commonplace for the dead to be buried with a concealed weapon. When a sorcerer dies, an undercurrent of panic can be felt in the community. Preventive methods range from having a reputable medicine man prepare the body for burial to outright cremation. The Ejagham people regard cremation as the ultimate dishonor to a man’s memory.

Social life in Inokun is dominated by groups. The two main group types are peer groups and sacred cults. Peer groups constitute a support system outside the family. They are responsible for planning weddings, birth celebrations, and arranging funerals for their members. They also function as cooperatives and financial houses. Sacred cults are the principal custodians of traditions and the medium for communicating with the gods. Most prominent among these is the Obasinjom.

In Ejagham communities, both in Cameroon and Nigeria, Obasinjom (or Basinjom) represents the voice of unerring prophecy. Its pronouncements are made manifest through an individual who takes on its persona while cloaked in the guise of an otherworldly creature. This wild masquerade ensemble drapes the body in a flowing robe and is crowned by a crocodilian head, adorned with a tiara of plumage. Characterized as a “speaking mask,” “the one who never tells lies,” and “the one who tells and acts,” Obasinjom unveils subterfuge and denounces wrongdoing. Such revelations form the core of Obasinjom’s dramatic

visual spectacle and are of vital concern to the well-being of its audience.

Instinct is the general term applied to unlearned behavior. Behavior is a result of neural wiring and the response of those circuits to sensory input, hormones, and internal feedback. In the early years of the 20th century, Ivan Pavlov studied conditioning of stimulus → response reactions to novel cues. His work led to J. B. Watson's formulation of "behaviorism." According to Watson, there were no instincts in animals; everything is learned—even respiration and the circulation of the blood. Behaviorism dominated psychology and the social sciences through at least 1970 and thus had a major impact on anthropological thinking.

The behavioristic formulation required viewing the inborn $S \rightarrow R$ units upon which conditioning operates as somehow not instinctive. Watson imagined that these building blocks were simple reflexes and arbitrarily excluded reflexes from innate behaviors; with reflexes gone, there was nothing instinctive left. More complex behavior was seen as a learned chaining of several $S \rightarrow R$ modules into a higher-level unit. Behaviorists thus became fixated on the study of learning.

Ethologists, the biologists who study animal behavior, found overwhelming evidence for complex innate behavior, and neurobiologists were later able to map the preexisting neural circuits that generate some of this activity, insect flight, for instance. Most

animal learning is now seen as a way of calibrating or fine-tuning behavior.

Animals are born with behavioral circuits; often, however, the behavior appears spontaneously later at a species-specific time, a process called *maturation*. Innate behavior is triggered by some combination of simple cues (*sign stimuli*); the sensitivity of the animal to these cues is controlled by motivation or drive (which may be hormonal or neural, depending on the behavior), so that inappropriate behavior is blocked and creatures can direct their efforts to responses with the highest priority.

Learning, where it can occur at all, is usually specific to each behavioral context; that is, the cues that trigger it, the cues that can be learned, and the way they are organized in the brain for later use are species specific. Learning thus serves to make behavior less dependent on the simple cues that initially guide the response (and, in general, the learning of the new cues).

In short, natural selection has acted to focus learning; in some sense, most learning could be called innate. Reexamination of behavioristic studies of pigeons and rats reveals substantial species-specific and context-specific biases in their learning. More recently, both biologists and psychologists have become interested in self-directed learning, planning, and concept formation—activities formerly considered impossible in animals by both behaviorists and ethologists. *Cognitive ethology*, as it is called, has shown that many of the intellectual activities once thought uniquely human are in fact widely shared. Whether these behaviors actually require thinking (in either humans or other animals) is another question.

 INTEGRITY, DYNAMIC

In the 20th century, value inquiry had been greatly influenced by numerous impressive developments in biology, anthropology, and psychology, as well as evolutionary ethics in natural philosophy and new concepts in process theology. This progress in the special sciences includes fossil hominid discoveries, wild ape behavior studies, and genetic engineering research. The differences between the four pongids (orangutan, gorilla, chimpanzee, and bonobo) and the human species are narrowing in light of this new evidence, while recombinant DNA and the human genome project offer awesome possibilities for neolife forms and an indefinite life span for the human species. Moreover, neurological experiments are clarifying the direct relationship between the functioning material brain and all mental activity. The convergence of these remarkable advances in science and technology challenges entrenched beliefs and old values, resulting in the foundation for a new philosophical anthropology and a new conception of intellectual integrity.

Since the conceptual revolution of Darwinian evolution in the middle of the 19th century, the fixity of species and the traditional commitment to eternal truths have given way to a process view of life and the reevaluation of all values in light of empirical evidence, critical reflection, a cosmic perspective, and the evolutionary framework. Also, the new naturalist paradigm needs to take both cosmic entropy and species extinction seriously. No longer is earth or life on this planet or humankind itself viewed as the center of this universe. Furthermore, the scientific viewpoint critically evaluates all religious beliefs and theological concepts within the context of human sociocultural history. In brief, the human species must now be seen as a recent event within sidereal reality.

Grounded in organic evolution and human experience, value judgments hold both short-range and long-range consequences for the adaptation, survival, enrichment, and fulfillment of our own species. The conflict between facts and beliefs, as represented in the widening gap between scientific evolutionism and religious creationism, can only be resolved in terms of an open-minded acceptance of empirical evidence and rational deliberation. In fact, the value of dynamic integrity (as one shall see) becomes essential for the progressive development of evolving humankind.

Following the Age of Enlightenment, naturalists in the early decades of the 19th century began to take the scientific investigation of rocks, fossils, and artifacts seriously. Beyond denial, the empirical evidence argued for a conceptual view of earth history alarmingly different from a strict and literal interpretation of the biblical myth of Genesis. The result is a greater understanding of and deeper appreciation for time and change as a direct outgrowth of ongoing research in geopaleontology and bioanthropology. This paradigm shift, from fixity to evolution in natural history, has a devastating effect on all those cherished beliefs and traditional concepts that had given the human being its alleged unique place and special value in this universe.

Charles Darwin

As a young naturalist aboard the HMS *Beagle*, Charles Darwin (1809–1882) always remained open to a wide range of empirical evidence and personal experience during his 5-year voyage of discovery (1831–1836). Even though receiving a degree in theology, he was willing to doubt the story of Genesis while taking seriously both the new facts and the new concepts in several earth sciences, for example, historical geology, paleontology, biogeography, and comparative morphology. Likewise, his evolutionary interpretation of organic history in terms of “descent with modification” (from a common ancestor), through natural selection and sexual selection, incorporated the theoretical frameworks of Charles Lyell in historical geology and Thomas Malthus in population dynamics; their critical interpretations of rock strata and reproductive changes, respectively, had resulted in a scientific framework for uniting humankind with nature and history.

It is to Darwin’s lasting credit that his analytic abilities were supplemented by a rational imagination. Through abduction, that is, the creative interrelationship of facts and concepts, he was able to elevate his own methodology above a strictly empiricist approach in order to correctly investigate the natural world in terms of time and change (geology and biology). This open orientation of synthesis allowed him to bring about a conceptual revolution in terms of the biological evolution of all life on this planet.

A comprehensive and intelligible interpretation of organic history was first presented in the pivotal writings of Darwin, especially in his major book, *On*

the Origin of Species (1859). Biological evolution replaced the eternal fixity of life forms. Yet in his epoch-making work, Darwin neither discussed human evolution nor considered the philosophical implications and theological ramifications surrounding the unshakable fact of organic evolution. Since our own species has emerged from an apelike form in the remote past, philosophers and theologians cannot ignore the reality that human beings themselves have created ethics, morals, and values within a natural environment and sociocultural milieu; one may speak of a human being as the evaluating animal, thereby distinguishing (but not separating) our own species from the apes and monkeys.

Clearly, scientific evolution both challenged and superseded the ideas and frameworks of Plato, Aristotle, Aquinas, Descartes, Kant, and Hegel (among many others). The certainty of previous values grounded in God-given laws or divine revelations could no longer be upheld by rigorous naturalists. As a result, the Darwinian conceptual revolution in modern science resulted in the emergence of both evolutionary ethics and pragmatic values in recent philosophy, as well as the emergence of sociobiology and evolutionary psychology in modern science.

Grappling with the implications of evolution, Thomas Huxley in England coined the word “agnostic” to express his own noncommittal position concerning the existence of God, while Ernst Haeckel in Germany advocated pantheism to express his dynamic worldview free from supernatural beliefs. In doing so, both evolutionists had acknowledged that the scientific fact of organic evolution has far-reaching consequences for those entrenched values of Western civilization that are grounded in traditional religion and theology. For over a decade, even Darwin himself had been reluctant to extend his theory of evolution to account for the origin and history of the human species (although Huxley and Haeckel did lecture on and write about human evolution during the 11 years following the publication of Darwin’s *Origin* volume).

Finally, in *The Descent of Man* (1871), Darwin himself argued that our species is closest to the great apes and shares a common ancestor, with the chimpanzees and gorillas, that would be found in the fossil record of Africa. The evolutionist now held that the human animal differs merely in degree, rather than in kind, from these two great apes; the bonobos of Africa had not been discovered yet, and the Asian orangutans now live only on the islands of Borneo and Sumatra.

Furthermore, Darwin claimed that the naturalistic basis of human morality had had its origin in those social instincts and altruistic feelings that have enhanced the adaptation and reproduction of evolving fossil apes and later protohominids followed by bipedal hominids. These instincts and feelings are visible in the behavior patterns of living primates (particularly in the four pongids).

The traditional static views of nature, life, and humankind have been discredited by science, reason, and a dynamic interpretation of this universe. Since the conceptual revolution of Darwinian evolution, a naturalistic framework has replaced all fixed, safe, and secure worldviews with a process perspective of material reality. Within a cosmic framework and from an evolutionary viewpoint, the narrowly conceived views of geocentrism and zoocentrism and anthropocentrism offered by previous philosophies have now been rigorously reevaluated and are found to be erroneous. Nevertheless, value inquiry does require a human-centered view of this universe if values are to be relevant, meaningful, and true for the human species.

Of the countless millions of species that have inhabited this planet (most of them now extinct), only one life-form has been able to philosophize on both its own existence, the natural environment, and ongoing history; one may speak of *Homo sapiens sapiens* as this evolving universe conscious of itself. More and more, through science and technology, the human species is capable of directing its ongoing evolution, as well as determining the future destiny of plant and animal forms on the earth and elsewhere. Today, one witnesses emerging teleology as a result of human intervention. This incredible power of control over life dictates that human beings must make those value judgments that will enhance their adaptation, survival, enrichment, and fulfillment: the wisdom of evolution shows that, as a species-conscious and evolution-aware form of life, humankind needs other plants, animals, and a suitable environment for its ongoing existence. Moreover, the inevitability of extinction is a brute fact for all life on earth and elsewhere.

Clearly, Charles Darwin had both intellectual and personal integrity; he was willing to change his scientific interpretation of nature as the integration of empirical evidence and rational concepts dictated. Darwin is exemplary of an open-minded and courageous naturalist, whose steadfast commitment to the controversial fact of organic evolution challenged both the engrained Aristotelian philosophy of fixed

species and the dogmatic Thomistic theology of divine causality.

Ethics, Morals, and Values

Within the perspective of evolution, what about ethics and morals and values? Surely, the fact that our own species has evolved from a fossil pongidlike form of the remote past has something very significant to say about the human being as the bipedal, culture-bound, language-dependent, reflective ape (fifth pongid or third chimpanzee) and its social behavior patterns.

To decide what is right or wrong, philosophers offer ethical principles to guide human behavior, for example, Aristotle's "golden mean" and Kant's "categorical imperative" (the emphasis may be on individual fulfillment or social harmony). Within an ethical framework, human conduct is judged to be moral or immoral, that is, specific acts are held to be good or bad in terms of ethical judgments that consider the individual and/or social consequences of human behavior.

As a philosophical naturalist, the biology-oriented Aristotle (384–322 BC) appreciated the social value of friendship and recognized the relativity of excess and deficiency (from individual to individual) in a person's striving to achieve excellence. Briefly, virtue ethics stresses the rational value of character development within a human society.

In sharp contrast to Aristotle, Immanuel Kant (1724–1804) ignored both evidence and experience in his quest for moral certainty. He universalized an act to determine its ethical worth, for example, he claimed that it is always wrong to tell a lie (otherwise, lying would have to be a moral law). Ultimately, Kant's categorical imperative is grounded in cryptic theology; the ideas of God, free will, personal immortality, and a divine destiny for ethical persons are invoked to justify following the categorical imperative. For Kant, these ideas are grounded in an assumed, unknowable, noumenal world (a metaphysical assumption unnecessary for any rigorous scientist or thoroughgoing philosopher of evolution).

Of course, neither Aristotle nor Kant was an evolutionist. Today, for the pragmatic naturalist, both ethical principles and moral judgments are seen to be recent products of human biosocial evolution, and as such, the quest for certainty in human conduct becomes very problematic indeed (particularly if appeals to divine intervention and/or a transcendent world are rejected).

Friedrich Nietzsche

It was Darwin, the English scientist, who woke the German philosopher Friedrich Nietzsche (1844–1900) from his dogmatic slumber. Evolution offered a new framework within which Nietzsche could ruthlessly analyze the place of humankind in this universe. Having claimed that "God is dead!" is a truth about reality, he then called for a thoroughgoing reevaluation of all values. His analysis found the philosophical ideas and religious beliefs of European civilization to be false values that have resulted in the pervasive mediocrity of human culture (as he saw it). No doubt with Plato and Hegel in mind, Nietzsche wrote: "The will to a *system*: in a philosopher, morally speaking, a subtle corruption, a disease of the character. . . . I mistrust all systematizers and I avoid them. The will to a system is a lack of integrity." For Nietzsche, constructing metaphysical systems for the sake of morality, particularly at a time witnessing the beginning of modern science with its bold evolutionism, was tantamount to childish deception.

Surely, however, one can be systematic and have integrity. Otherwise, it is difficult to see how the human species will endure in its never-ending struggle within evolving nature.

Nietzsche was correct to criticize a blind adherence to any static metaphysical system or rigid theological framework. In fact, he himself desired to systematize his own iconoclastic and dynamic worldview. Taking a cosmological stance, Nietzsche argued that both space and energy are finite, but time is eternal. Therefore, for him, this universe is a cycle of evolution and devolution; this cosmic cycle has been and will be repeating itself in an absolutely identical way throughout all eternity. Of course, there is no progressive evolution from cycle to cycle, since each cosmic cycle is the same.

Concerning interpretations of dynamic reality, the arc of evolution spans from mechanistic materialism to spiritual mysticism. Nietzsche's own interpretation of evolution is grounded in creative vitalism. Furthermore, for Nietzsche, this universe is essentially the will to power and the human, all-too-human species is merely a temporary link between the past ape and the future overman (a superior being who will create new values beyond the traditional conceptions of good and evil).

Nietzsche said "Yes!" to the eternal recurrence of the same reality. Moreover, in this dynamic universe

of organic evolution, he stressed the essential value of human creativity and, as an atheist, challenged the human species to create new values that are free from religion and theology. Invoking his eternal recurrence perspective, Nietzsche taught that an individual must affirm life by willing to live it as if each choice one makes is a judgment for all eternity. Consequently, for him, each moment has eternal value.

Unfortunately, Nietzsche failed to clarify his own views on truth, science, and naturalism. Even so, this iconoclastic philosopher did have integrity, as is demonstrated in his scathing criticism of outmoded beliefs and in his desire to incorporate the findings of science and the use of reason in order to verify his awesome idea of the eternal recurrence of this same universe. It was Nietzsche's steadfast commitment to both overcoming mediocrity and the quest for wisdom that elevated his cosmic vision above the pervasive pettiness of human existence (as he interpreted it).

Naturalism and Pragmatism

Before the writings of John Dewey (1859–1952), the pragmatists Charles Sanders Peirce and William James had been influenced by the evolutionary movement in the special sciences. All three thinkers represented the crucial transition from religious idealism to philosophical naturalism in American thought.

For the modern pragmatist as evolutionary naturalist, science has epistemological priority, and matter (energy) is the ontological makeup of this dynamic universe. This practical philosophy does not dogmatically rule out theoretical constructs or rational speculations, but it does require factual evidence to justify objective truth-claims about our species, human society, and the natural world.

In step with the new logic of evolution, Dewey developed a pragmatic naturalism that stressed a need for philosophy to accept the advances in science. In particular, the discoveries of Galileo and Darwin had reshaped earlier interpretations of concrete nature. And for Dewey, philosophy has an obligation to incorporate these new scientific findings into its worldview.

In his insightful essay "The Influence of Darwin on Philosophy" (1910), Dewey pointed out the sharp contrast between change and fixity. He held that a modern thinker must acknowledge the superiority of the scientific method, as well as the flux of both human knowledge and nature itself. With sensitivity

to the modern situation, Dewey wrote: "We live in the twilight of intellectual transition." Like Nietzsche, Dewey knew that the conceptual revolution of Darwinian evolution foreshadowed the transformation of false beliefs, old values, and static worldviews.

Ignoring science, many phenomenologists and existentialists had adopted a subjectivist stance in sharp contrast to the naturalist attitude, not to forget the antiscientific menace of fundamentalism and the intellectual nuisance of postmodernism. In the tradition of philosophical naturalism, Marvin Farber (1901–1980) taught that the human species is totally within nature; the fact of evolution had successfully shaken him free from a narrowly conceived phenomenology (which he eventually came to see as a limited methodology incapable of delivering a true ontology, sound epistemology, and humanist ethics).

Farber appreciated the obvious value of Darwinism for a sound naturalist philosophy. Reflecting on the liberating influence of evolutionism from spiritualism, he wrote: "Although philosophical criticism had long before anticipated this result, it was the large array of scientific evidence offered by Darwin which delivered the most distressing blow to the supernaturalist." Ultimately, the Farberian outlook is grounded in humanist values and pervasive materialism.

Despite their adherence to social change and organic evolution, John Dewey and Marvin Farber still clung to an outmoded idea. Although rejecting Hegel's idealism, Dewey retained an ambiguous conception of God inconsistent with a succinct naturalism; even so, he was not a practicing believer. Although rejecting Husserl's idealism, Farber remained sympathetic to Marxism even though it stifled intellectual creativity; moreover, he had never visited the Soviet Union. Nevertheless, by embracing science and reason, each philosopher did represent a significant degree of dynamic integrity.

Dynamic Integrity

An enlightened thinker is acutely aware of deep space, deep time, deep evolution, and deep psychology. Unfortunately, recent philosophy is usually detached from the incredible discoveries and awesome perspectives of modern science. This universe encompasses billions of galaxies; Earth is billions of years old; the process of organic evolution results from those random variations that occur in the biochemical complexity of the DNA molecule; and unconscious

activity motivates human behavior. Furthermore, beneath all the myriad evaluations of the human being lies a deep value: this is the virtue of integrity. But as a direct result of scientific cosmology and modern anthropology, no longer can the human species cling to a static worldview, that is, no longer can it be dogmatically committed to a myopic and closed philosophy, fixed moral maxim, or universal ethical principle (Aristotelian fixity and Kantian certainty have given way to evolutionary pragmatism).

It is now necessary for emerging humankind to recognize the quintessential need for a dynamic integrity that understands and appreciates the obvious fact of evolving nature while remaining in step with the advances of science and technology. Dedicated to a neo-Enlightenment and open inquiry, dynamic integrity integrates scientific findings, process cosmology, and evolutionary naturalism into a comprehensive and intelligible philosophical anthropology that encourages both creating and reassessing human values. Such an interdisciplinary attitude fosters a holistic character that is amenable to social change, critical dialogue, and pervasive investigation.

Yet, dynamic integrity must mean more than simply living an ethically integrated life or merely having a morally unified self. Instead, it entails an open-minded and open-ended commitment to science, reason, compassion, new perspectives, and the betterment of the human species. In principle, dynamic integrity is evolution based, for example, it acknowledges the unity of self, the unity of humankind, the unity of life, and the unity of this universe.

Dynamic integrity requires the creative union of thought and action. A person has dynamic integrity when his or her actions are not only based on empirical evidence and logical reflection but also when these actions contribute to the adaptation, survival, enrichment, and fulfillment of human beings. Consequently, in terms of ethics and morals, dynamic integrity is both deontological and teleological in nature: there is a duty to accepting scientific evidence, as well as an ongoing commitment to improving the human species by increasing knowledge, freedom, happiness, and longevity.

Briefly, dynamic integrity is both an attitude of mind and an approach to life that acknowledges the immensity of this universe, the brevity of human existence within it, and the ongoing need to enhance our species through scientific knowledge, critical thought, and resolute effort.

In evaluating their creative lives, both Darwin and Nietzsche represented a commitment to the essential value of dynamic integrity: Darwin revolutionized science through his giving attention to the facts of geobiology and their far-reaching implications for life in terms of evolution, while Nietzsche rejected the falsehoods and mediocrity of modern civilization and, subsequently, challenged the human species to create new values.

Pierre Teilhard de Chardin

The geopaleontologist and mystic Pierre Teilhard de Chardin (1881–1955) demonstrated dynamic integrity by embracing evolution, even though he was silenced by the Roman Catholic Church for his unorthodox ideas and perspectives. This courageous Jesuit priest had accepted and incorporated into his faith the facts from geology, paleontology, biology, and anthropology (even though this convergence of empirical evidence required a new interpretation of humankind within nature that challenged traditional beliefs and old values). In sharp contrast, many of today's creationists choose to reject or ignore any empirical evidence that may discredit their faith, theology, or perspective.

Unfortunately, the Harvard scientist Stephen Jay Gould lacked dynamic integrity when, without sufficient evidence, he implicated Teilhard in the infamous Piltdown hoax and thereby besmirched the Jesuit priest's reputation. Furthermore, Gould criticized Teilhard's theistic evolutionism. Ironically, this is despite the fact that Gould himself clung to an outmoded and unwarranted ontological dualism by advocating the existence of two separate realms of inquiry: the natural world of the scientist and the transcendent world of the theologian (at least Teilhard had attempted to bridge these two realms in terms of an evolving and converging spiritual panentheism). If one takes Gould seriously and assumes that these two different realms do exist, then how do they influence each other in any meaningful way? Under rigorous scrutiny, Gould's dualism quickly becomes completely superfluous for the evolving human species.

Regrettably, because of his dualistic approach to naturalistic neo-Darwinism, Gould is being used by biblical fundamentalists and religious creationists to discredit the fact of evolution. A rigorous evolutionist (with dynamic integrity) realizes that there is only this material universe, and that the emerging human

species is a product of, dependent upon, and totally within it.

The spread of fundamentalism and creationism in our modern world clearly illustrates a growing resistance to science and reason, not to mention a lack of vision for the future of humankind. Unfortunately, the gap between facts and beliefs continues to widen. In particular, the rejection of an evolutionary framework by some philosophers and many religionists clearly demonstrates that internal consistency alone in a worldview is not the road to truth and wisdom. In the ongoing quest for both truth and wisdom, dynamic integrity is always necessary.

And today, more and more, the potentially rational and sometimes compassionate human species needs to value those new ideas and collective actions that will contribute to its survival and fulfillment (in sharp contrast, by rejecting science and reason, all supernatural worldviews are bound to fail because their beliefs will be discredited by empirical evidence). Evolutionism forces one to look at this universe, life on earth, and the human species in a radically new way. Change is an invitation to improvement, and humankind must now choose evolution over stagnation. To save biodiversity and civilization, it is the deep value of dynamic integrity that becomes the axiological foundation for the emerging human species on earth, as well as its ongoing evolution elsewhere in this universe.

Pierre Teilhard de Chardin had called for an ultra-anthropology that views our species within an ever-widening comprehensive framework. In the future, scientists and philosophers will need to remain open to compelling evidence and progressive concepts if their thoughts and actions are to be relevant, meaningful, and true. For the evolutionary naturalist, philosophical inquiry must be in step with scientific discovery. In short, dynamic integrity underpins both pragmatism and materialism. As such, dynamic integrity is the essential value for wise social conduct and purposive creative intelligence throughout the centuries to come.

Quo Vadis

Our hominid species is the result of 7 million years of Darwinian evolution from fossil apelike forms to the human being of today. Only a complete disregard for modern geopaleontology and bioanthropology would prevent one from recognizing the established

fact that the human being represents a recent species within primate evolution. For an evolutionist, our own species is the successful great ape that dominates this planet because of its sustained bipedality, social behavior, material culture, and symbolic language as articulate speech.

But the human species is not a fixed animal within organic history and sociocultural development. Furthermore, humankind is not nailed to the earth. Despite global convergence but with critical optimism, one may speak of the future divergence of our species beyond this planet as the human being becomes the cosmic ape among the stars.

As the human species continues to evolve on earth and elsewhere, space exploration along with nanotechnology and genetic engineering offer a Nietzschean vision: the emergence of godlike overbeings in the ages to come. No doubt, the human being has only glimpsed the awesome powers of science and technology in terms of both manipulating and directing the process of organic evolution. Our future generations will probably enjoy an indeterminate life span and see the artificial creation of neolife forms (i.e., new species of plants and animals), as well as the alteration of the human species for its adaptation to and survival in new environments, for example, living in outer space and on other worlds.

The planetary fallacy (as this author calls it) erroneously maintains that life, organic evolution, and intelligence are restricted only to the earth. Such a myopic viewpoint rejects the probability of both exobiology and exoevolution in this dynamic universe. Admittedly, the serious consequences of ongoing evolution challenge those values that many adhere to today, especially the claim that the human species is absolutely unique in reality. Overcoming the planetary fallacy, one should embrace a truly cosmic perspective in which humankind has the courage to explore outer space and to evolve into a superior form of life in terms of both intelligence and technology. As such, one may speak of the emerging cosmic ape as the brave and curious terrestrial human species ventures into sidereal space (a momentous transition for planetary life that has already begun). Of course, our cosmic destiny will require that humankind solve those future problems that are inherent in adaptation, survival, and evolution among the stars.

For the pragmatic naturalist, meaning and purpose in human life are derived from, and value judgments are made within, material existence. No doubt,

continued progress in science and technology, as well as an ever-widening perspective, will result in a reevaluation of our present values. Surely, many centuries from now, the old values of the Judeo-Christian-Islamic religions and Eastern philosophies will be replaced by new values (assuming that the human species survives on this planet and/or elsewhere). And there is always the crucial need for ongoing inquiry in order for humankind to overcome both intellectual stagnation and psychological boredom.

Likewise, a community of inquirers will be necessary for the continuing evolution of *Homo sapiens futureensis* as it engineers this solar system and others for its survival and fulfillment among the myriad of galaxies throughout this universe. For the success of this cosmic adventure, humankind must affirm both the joy of life and the value of existence.

Furthermore, the human species must overcome the omega illusion (as this author sees it). In the 20th century, Pierre Teilhard de Chardin offered a mystical vision of the final end-goal for human evolution on earth and then beyond it. His speculations appeal to the psychological needs and emotional desires of the human species (especially in light of the certainty of death). But the wish for personal immortality is no proof that such a status is true or even possible.

Without evolution, nothing makes sense. The pragmatic naturalist acknowledges the development of our modern worldview, from Julian Huxley's religion without revelation to Richard Dawkin's evolution without theology; one may speak of the development of values from the sacred to the secular. In this context, the backsliding from material evolution by some renowned thinkers is deeply regrettable and clearly demonstrates a failure of nerve. Of course, there is always the human need for love, compassion, and responsibility (aspects belonging to the naturalist outlook and dynamic integrity).

Finally, there is always the need to establish ethical guidelines for scientific research that must value nature, life-forms, humankind, and critical thought. Since the groundbreaking contributions of Charles Darwin and Friedrich Nietzsche, the brute fact of organic evolution and the empirical findings of the special sciences continue to reinforce a materialist framework that is paving the way for a cosmic neo-Enlightenment free from nonsense, ignorance, superstition, and obscurantism. With dynamic integrity as its essential guideline, the pragmatic human species will continue to make substantial progress in terms of

both utilized scientific truth and shared philosophical wisdom.

Intelligence is a concept that is believed to be made up of a set of complex behaviors. It is described as the ability to problem solve, to perceive objects in one's environment, to understand spatial relationships, to remember, classify, calculate, and reason. It is analogous with *cognition*, a mental quality comprising one's ability to learn from experience, to adapt to new situations, acquire knowledge, and deal with abstract concepts. It has been found to be clearly associated with the integrity and functioning capacity of one's central nervous system functioning (the brain) and is made up of several anatomically related domains (e.g., arousal and alertness, visual spatial processing, attention, memory, executive functioning, etc.).

Raymond Cattell suggested that intelligence consists of two parts, “fluid” intelligence (one’s innate basic reasoning that is supposedly independent of culture and educational background) and “crystallized” intelligence (the information and skills one learns through education, experience, and socialization).

Many scientists and educators believe that intelligent behavior is not restricted to human behavior; that is, it can be exhibited by other species. However, it is assumed to be limited by the absence of language. *Language* is defined as a culture’s representation of ideas and objects in symbolic form that is used classify and store information in memory. Only the species of *Homo sapiens* has developed the ability to string together several sounds (phonemes) to produce new meanings. Language is considered a critical component of higher-order intelligence because without it, one could not measure and define the more complex aspects of intellectual behavior.

Integral to the current use of the term intelligence is the intelligence quotient (IQ). An individual’s IQ is commonly measured and quantified by paper and pencil, individually administered IQ tests, as well as by the appraisal of adaptive behavior (based on how a person functions in an everyday setting).

Evolution of the Brain

In all species, the brain is the organ most associated with “intelligence.” Much of the human brain’s evolution has occurred within the past 5 million years, during which time it has increased 5 times from its original size. The modern human brain weighs between 1,000 and 2,000 g.

Current theorists believe that our earliest bipedal ancestor was the East African *Australopithecus*. Anthropological evidence indicates that its brain weighed about 400 g (the same size as a modern chimpanzee’s). They evolved into the species *Homo habilis*, a toolmaking hominid characterized by dental patterns similar to modern humans. *Homo habilis* developed a significantly larger brain than its predecessor’s (believed to weigh one half the size of modern man’s brain), which was thought to be directly related to their scavenger lifestyle. This type of lifestyle would have been more reliant on the organism’s sensory, motor, and social skills than that of the *Australopithecus* lifestyle. It is thought that *Homo habilis* continued to develop its skill in designing and implementing tools until it changed from scavenger to hunter and migrated out of Africa.

These new behaviors were exhibited by *Homo erectus*, a species characterized by a larger brain and the behavior of traveling. Fossilized remains of *Homo erectus* have been found in Africa, Java, and Peking. As a hunter-gatherer living in a complex sociological society, survival of *Homo erectus* was strongly influenced by their ability to read another’s behavior and adjust their own based on experiential and motivational factors.

The role of preadaptation may explain the continued development of brain size in early man. Once certain intellectual behaviors (such as extended travel and toolmaking) had developed that could enable a species to take advantage of their environment, it opened the door for new cognitively superior developments to emerge. Dean Falk suggested that the development of the upright posture of *Australopithecus* contributed to the development of new changes in the venous blood flow of the brain. Until that point, apes had reached an upper limit to the growth of their brains due to the oxygen consumption and generation of heat in the brain. Exercise (like that involved in travel) put the species at risk for overheating the brain, until they developed a more widely dispersed venous blood flow system that served as a cooling system and allowed for the advent of extensive movement. Once upper limits of growth were selected out, other influences were free to contribute to brain growth (e.g., increased social development, climate adaptation, diet changes, increased skill in movement, larger bodies, mate selection).

Scientific discoveries of this type have contributed to the theory that the anatomical increase in brain size is responsible for producing more sophisticated behavioral abilities. It would stand to reason, then, that the more “sophisticated” the species, the more specialized central nervous system (CNS) functional domain areas. That is, as the human brain has evolved in size, it has actually developed more functions, which allows, in turn, more advanced skills to evolve.

Western Versus Eastern Views on Intelligence

The Western concept of intelligence can be traced back to ancient Greece, when Plato described three aspects of a human’s soul as comprising intellect, emotion, and morality (later renamed as cognition, affect, and conation). Cicero appears to have coined the term “*intelligentia*,” and St. Augustine defined

intelligence as quickness of understanding and acuteness of discernment. Prior to the late 1800s, when Alfred Binet developed a paper-and-pencil test to measure it, intelligence was considered a philosophical concept and could not be easily quantified.

Early Eastern views of intelligence were also grounded in philosophy, although their understanding originally evolved from the Indian concepts of wisdom and prudence. Over time, this concept of intelligence (aka *buddhi*) was expanded to encompass human emotion, societal values, and interpersonal relationships.

History of Intelligence

Scientific research aimed at quantifying and identifying human intelligence began as early as 1869, when Francis Galton studied individual differences in the biological underlay of cognitive functioning by measuring reaction time and determined that all humans possessed a “general” intellectual ability.

This modern, Western concept of quantifiable intelligence scores was further developed and popularized during the 1910s by German psychologist Wilhelm Stern, and the continued work of Lewis Terman. They were responsible for expanding the intellectual concept of “mental age” into a quotient by computing a formula that divided mental age by chronological age and multiplying by 100.

The idea that a mathematical score could represent one’s overall intellectual functioning was truly expanded by the infamous French psychologist Alfred Binet and his colleague Theodore Simon, with their development of an empirical measure of mental retardation (Binet-Simon Intelligence Scale, 1905). They were the first to use age standards in measuring intelligence, and their scale was designed to compare a mentally retarded individual’s score with that of their normal, same-age peers.

Both Henry H. Goddard and Lewis M. Terman revised Binet’s original intelligence scale and adapted it for use within the United States in 1916, with several revisions following in the years of 1937, 1960, 1972, and 1986. To date, it is still one of the most popular intelligence assessment measures used.

Meanwhile, as Binet and his predecessors continued to perfect their empirical measure of human intelligence, a Swiss biologist named Jean Piaget developed a theory that depicted intelligence not as a “general” ability, but rather as a continuum of human

development and biological adaptation. He described the way a child typically perceives, understands, and operates in their environment as a cognitive process that progresses through time as a result of the reorganization of psychological brain structures. Piaget theorized that intellectual development occurred throughout four childhood stages, starting at birth, and each stage allowed for the construction of increasingly complex intellectual processes. Because he believed intellectual ability could be impacted by both biological and genetic factors, he thought it to be malleable.

It wasn’t until the late 1930s that scientists began to describe intelligence as not just a single general ability, but as a cluster of cognitive processes (e.g., information processing, attention, planning, forming strategies, etc.) that, as Piaget had suggested, could grow and develop over time and were influenced by both cultural and social factors.

Louis L. Thurstone postulated that intelligence was actually made up of as few as seven independent mental abilities that operated independently, and in 1939, American psychologist David Wechsler developed the Wechsler-Bellevue Intelligence Scale test in an attempt to tease out and measure these different underlying mental abilities by providing distinct scores for each area of functioning.

In 1983, Howard Gardner added to this theory, claiming the concept of multiple intelligences could be further broken down into cognitive components that could describe specific behavior. However, when these distinct functions were taken in whole, they would better describe the overall cognitive performance of an individual. He added the specific concepts of musical, bodily kinesthetic (athletic ability, dancing), logical-mathematical (numerical ability), linguistic (verbal ability), spatial (orientation in space map reading, visual arts), interpersonal (understanding the behavior of others, empathy, sympathy) and intrapersonal (understanding oneself) functioning to the theory of intelligence.

Soon after, William Sternberg expanded the theory of intelligence to encompass the sociocultural context in which humans behave and interact. He redefined intelligence as a purposeful, goal-oriented behavior that could not be understood outside of an individual’s environment, including a person’s practical knowledge as measured by their success in the real world, not by a generic, quantifiable number.

Qualitative and Quantitative Intelligence Measurement

Intelligence is extremely difficult to identify and measure, as it is a complex process that involves many types of behavior. Intelligence tests were primarily designed to allow for an objective, systematic observation of an individual's intellectual performance in a controlled situation. However, it is obvious that no single IQ test or theory can fully identify the full spectrum of intelligence, particularly the individual's ability to use both environmental and personal resources to adapt to the world. Despite that, standardized intelligence scores are used in many industrialized societies as a basis for selection, placement, and decision making in educational and employment arenas across an individual's life span. They also play an enormous role in the decisions of allocation of the society's resources and opportunities. Although IQ tests cannot tap into every aspect of intellectual functioning, a good intelligence test should be both reliable and valid and ought to include both clear and ambiguous items that vary in difficulty. Commonly used measures of intelligence provide scientifically collected age- and/or education-adjusted comparative data that are normally distributed amongst the population. Currently, the average IQ as measured by the Wechsler Adult Intelligence Scale is a standard score of 100 (+15), where mentally retarded people score below 70, and gifted at or above 130.

INTELLIGENCE AND GENETICS

Intelligence is the term used to measure the speed with which learning takes place, how well something is learned, how long it is remembered, and how well it is remembered. Intelligence also deals with much more than lessons learned in schools. Intelligence involves being able to remember things, ideas, or physical actions that have been learned. It also involves responses to challenges and to the need for innovative creativity.

Intelligence as a general cognitive ability is a universally recognized phenomenon, but there is not a universal definition to precisely explain it. It clearly involves in humans the ability to acquire language, to solve problems, to understand things and ideas.

Humans differ widely in their abilities to learn, remember, solve problems, or understand. The speed with which these tasks (and others) are performed is used to measure intelligence. Thus, people who can learn a language or solve mathematical problems more quickly than others are considered to be more intelligent.

IQ tests can measure the intelligence of a person in a particular culture. The tests can measure intelligence in terms of the speed of the mind's ability to solve problems.

However, IQ tests do not measure intelligence as a response to environmental challenges. People differ in their abilities to handle different situations. In the face of natural disasters, events filled with dangers, or stressful situations, individuals with school "smarts" may not have survivor "instincts."

Creativity is also a part of intelligence. Inventiveness and creativity are responses

sometimes to necessity. However, in the case of the performing arts, such as music and drama, creativity is an intelligent act that may be partially due to training.

Consequently, understanding intelligence involves both biology of the brain and the cultural experiences of people. This is often expressed as "nature versus nurture."

Intelligence is a factor of both genetic heredity and environment. Every human is born with mental capacities. These can be nourished or undernourished, both physically and culturally. If an infant or child is malnourished or neglected, abused, or discriminated against because of race, creed, nationality, or physical handicap, he or she is likely to underperform in mental capabilities. However, if a child is nourished physically and culturally stimulated, he or she is very likely to exhibit socially acceptable intelligent skills and behaviors.

Controversy rages over intelligence. Because humans differ in intelligence, this creates inequalities. The inequalities have been associated most often with social conditions or with race. Claims of racial inferiority due to genetics have been advanced in the past; however, studies of the genetic base of human intelligence are still in their infancy. Studies of twins have strongly indicated that all of intelligence is not due to personal biology, but to other factors as well.

— Andrew J. Waskey

IQ TESTS

"IQ" stands for "intelligence quotient." A person's IQ is a number used to indicate a person's "mental age" in comparison with others who have taken the same test. IQ is then used as an indicator of intelligence. An IQ for someone is calculated by dividing his or her mental age by chronological age. Therefore, if an 8-year-old has a mental age of 12, his or her IQ will be the mental age of 12, divided

by 8 years of age, which equals 1.5. This number, after 1960, was multiplied by 100 to obtain a score, in this case an IQ of 150.

Since the 1960s, the number 100 has been set as marking average intelligence. Those with IQs below 100 are considered below-average intelligence and those above 100 are above-average intelligence. However, in recent decades, this has been replaced by a statistical "Z score."

IQ tests were first developed in France in 1904 by Alfred Binet. He invented the Binet Scale (Simon-Binet Scale) in order to have an objective method for distinguishing between normal children and those whose mental capacity was such that they could benefit from special education.

In 1916, Lewis M. Terman published a revision of Binet's work: the Stanford Revision of the Binet-Simon Scale of Intelligence, or Stanford-Binet, for short. It would be the primary intelligence test used in the United States for decades thereafter. However, problems arose. Terman believed that intelligence was fixed. Therefore, once a child had been tested, the child was labeled by the test results. For many critics, this stamped a child with a mark of inferiority (if applicable) for life.

Another issue is the meaning of intelligence that IQ tests are supposed to measure. "Intelligence" has never been precisely defined. This means that there is an open question as to what exactly an IQ test is measuring.

Other issues have arisen from the recognition that children who come from families that travel and provide rich learning environments score higher than children who come from impoverished homes. Enrichment programs such as Head Start have demonstrated significantly increased IQ scores when children from underprivileged homes are enriched by the program. Physical hunger due to poverty, fatigue, illness, or family stresses may also affect performance.

Cultural bias is also a controversy in IQ tests. Immigrant children taking a test in a new language and culture may encounter difficulties. Efforts to create culture-free tests have not been completely successful.

COGNITIVE SCIENCE

Biological anthropologists who study the field of cognitive science, which examines ways in which the human brain affects complex behaviors, have expressed interest in the work of psychologist Ellen Bialystok of Canada's York University and three coresearchers who concluded that being bilingual may prevent brain deterioration as individuals age. The three studies were designed to test the hypothesis that the same cognitive processes that control the ability to remain focused on one task while ignoring irrelevancies are those employed in using two languages. Building on previous research on children and young adults, the researchers were interested in discovering if the same findings held true for older adults as well as for younger individuals. Bialystok et al. found that individuals who knew and used more than one language scored higher on simple cognitive tests than those who knew and used only one language. The tests also revealed that advantages from bilingualism increased with age.

To control for other variables, the individuals involved in the studies all came from similar socioeconomic backgrounds and had been bilingual for most of their lives. One hundred and four respondents ranged in age from 30 to 59, while 50 others ranged from 60 to 88 years old. The researchers developed their tests of cognitive skills using the Simon Test, which operates on the principle that when a brain is faced with cognitive clashes, reaction time will slow down as the human brain processes information and determines proper responses.

The researchers developed cognitive tests employing a system of flashing red and blue squares that were placed on either the right or left of a computer screen. After identifying the squares, individuals were asked to respond by pressing the left shift key on the computer keyboard if the square was identified as blue or the right shift key if the square was perceived as red. Reaction time was delayed when respondents were forced to press a shift key on the opposite side of the keyboard from where the square appeared on the computer

screen, as was true in approximately half of the required identifications.

The two-square test was followed by an additional test, in which respondents were asked to work with squares of four colors. In this case, the squares were located in the middle of the computer screen. As expected, bilingual respondents again received higher scores than other respondents. As the task was repeated a number of times and identification became routine, differences in the scores leveled off. The overall conclusion from the three studies was that bilingualism increases the ability to perform across a wide range of complex cognitive tasks, even as individuals age.

INTERCULTURAL EDUCATION

Intercultural education may be viewed as an application of cultural anthropology to the design and implementation of formal educational curricula, largely in prebaccalaureate programs. Its goal is to instill in students an appreciation of other cultures so as to offset a dogmatic and unproductive ethnocentric worldview. In an interconnected world where the capability to deal effectively with cultural differences is a necessary skill, this is an admirable educational program, but one beset with challenges.

The Related Approaches of Anthropology and Multicultural Education

Intercultural education is somewhat distinct from both the teaching of anthropology and multicultural education for elementary and secondary students. An anthropology course, while it may achieve the same goal as intercultural education, is designed to describe the ideas and methods of social science, based largely on what anthropology has learned about human cultural variation, the origins of humanity, and the rise of civilization. In this, it is broader in scope and less focused on transforming students' ethnocentric views. An anthropology

course will spend most of its time describing the methods of anthropology, the fossil record and what inferences can be drawn from skeletal and artifact remains, and, more to the point of intercultural education, what anthropology has learned about cultural systems and the range of variation exhibited in these by societies around the world. A student may do well in such a course but not come to the transformational understanding required for intercultural education.

Intercultural education is not specifically tied to anthropology as a discipline, especially an anthropological approach that dispassionately presents a description of humanity. Rather, it seeks to persuade students that there is an inherent value in other cultures. In this regard, it may be imbedded in any course (e.g., English, language, social studies). The findings and conceptual approach of cultural anthropology may inform and guide it, in concert with allied fields such as sociology, speech communication, psychology, and world history, but may not be directly identified with it.

Intercultural education is also distinct from multicultural education, although it blends into and overlaps with it. Multicultural education focuses more on cultural pluralism within a nation and, in support of this, strives to present pedagogical materials from a variety of perspectives (by ethnicity, gender, social class, etc.). This is done in order to provide students of diverse backgrounds with materials that they can

identify with and thereby gain some measure of ownership of their educational experience and close gaps in achievement.

Intercultural education is designed to create in students an improved worldview, one that includes an appreciation for the broad range of human cultural capability and expression. In other words, it is the educational application of the anthropological dictum that the members of all human groups possess an equivalent level of intellectual competence and a cultural system that is well

formed and valid. This anthropological view of humanity is associated with two seminal orientations about how humans and human culture should be studied. These constitute the basis of an intercultural approach, as well as its challenges, in elementary and secondary education: a comparative approach to learning about humanity and the analytic skills to perceive practical and ideological value in other ways of life, or cultural relativism.

Comparative or Cross-Cultural Approach

Students may be told that humans are all equally capable, but an anthropological approach would hold that this conclusion must be supported by convincing accounts depicting humans of different cultures effectively dealing with appreciable challenges in their daily lives and environment. Selecting texts presents a challenge of combining the often mutually incompatible demands of interest (the materials should be written at an appropriate level and also be dramatically compelling to engage the willing involvement of the student) and validity (the materials must be reliable or realistic as to the relevant features of another culture). Anthropology carries the added burden in that much of what it describes about other cultures, such as forms of religion, marriage, and sexuality, may be considered unsuitable as instructional materials in elementary and secondary schools. For example, Margery Wolf's readable account of a Taiwanese

family (*The House of Lim*) necessarily includes accounts of prostitution, gambling, and arranged child marriage. The goal is to introduce students to other lifeways, yet some of these will be problematic to students, and probably more so to their parents/guardians. Educational curricula, especially in the United States, must meet community standards, and just as with the controversy over the teaching of evolution, pedagogical materials that present religious, marriage, and political systems of other cultures as explicitly valid (and, in effect, equivalent to corresponding local systems) may meet resistance.

Anthropology has long been familiar with case studies reasonably short ethnographies, used individually (e.g., the Holt, Rinehart & Winston series, *Case Studies in Anthropology*) or in readers (e.g., *Service's Profiles in Ethnology*). However, these were designed for college courses and thus were in the realm of adult literature and may be unsuitable for grades below the last years of high school. There has been a substantial growth in texts about other peoples in the world designed for elementary and beginning secondary students, but these have not always managed to merge interest and realism. There has also been a substantial growth in visual materials dealing with other cultures, especially in educational television. Many of these productions have focused on the life experiences of youth, with the expectation that this is what will interest, and will be appropriate for, an elementary and early-secondary-school audience. The irony of the success of these materials is that while they may very well be absorbing and valid in their representation of younger people in other cultures, it is really the world of adults whose valid worldview and cultural practices international education must present in a convincing light.

Another issue in the preparation and selection of cultural descriptions is that of standardization. If one goal is to present the idea that different religious systems can provide equally satisfying ways of community worship and integration, then there must be a number of written and audiovisual materials that present religious beliefs and rituals in comparable ways. Students who are examining, for example, how forms of worship may support forms of subsistence should have access to works that provide sufficiently comparable descriptions of these aspects.

It is necessary, from an anthropological standpoint, that the effort to make the rest of the world valued must be vested in valid and reliable knowledge

of other ways of being human. Gaining an effective and lifelong appreciation of other cultures has to be based on the sometimes unpleasant reality of different customs and not simply presented as simply a good and enlightened perspective. An intercultural education informed by anthropology must continue to locate and develop pedagogical materials that meet the challenge of explicating different cultural worlds.

Cultural Relativism

The second anthropological contribution is cultural relativism. This is the analytic orientation that other, and especially quite different, cultural systems can be demonstrated as providing valid, productive, and satisfying ways of being human given the environmental and sociocultural situation of the society. An excellent set of comparative pedagogical materials by itself is not sufficient for the goals of intercultural education. A student may read or view a variety of ethnographic accounts and even enjoy and be stimulated by the experience, yet still be unconvinced that any of these represent valid human ways. It may even be the case that the degree of enjoyment at vicariously learning about "strange" ways is directly proportionate to the degree of certainty that these other practices are not only "strange" but abnormal.

Thus, the challenge is to place comparative materials in an instructional framework that provides students with the intellectual and affective ability to confront (not necessarily approve of and adopt) other cultural ways and then to understand that these may make sense. They have to be understood as possessing an appropriateness within a functioning cultural system that provides workable solutions for certain social and environmental problems and opportunities. This challenge may not be able to be overcome, at least within the confines of formal education. Achieving what has been referred to as "transpection," the ability to convincingly project oneself into very different ways of thinking and behaving, seems overly utopian. This cognitive condition, it should be emphasized, is not being done by an assimilating immigrant to whom its success or failure has serious real-world consequences, but rather as a class project or homework assignment. Furthermore, intercultural education is not well served by a negative approach that implies that other cultures are successful simply by critically detailing the purported flaws of the national culture. Nor is it achieved when

the world is depicted as made up of “good” societies (third-world or underdeveloped societies) or “bad” societies (industrialized first-world or powerful Western state systems). Rather, a convincing case must be presented that explains a rationale for another culture’s practices and ideology. Anthropology has often achieved this by placing another culture in its social and physical environment. Providing accounts of breast-feeding until the fourth or fifth year due in part to a protein-poor tropical environment, of sororal polygyny due to the importance of the cowife bond and a cooperative women’s work group, or of the prohibition on beef consumption in Hindu India due in part to the value of cattle dung have been staples of anthropological relativistic explanation. These and many others have to be presented effectively and convincingly in relation to the data that students obtain from their comparative materials in order for intercultural education to be successful.

Intercultural Education as a Luxury

Intercultural education may be viewed as luxury (even an irrelevance) compared to the acquisition of skills such as computation, literacy, citizenship, national culture, and subsistence/occupation technologies. It is important for the world’s great powers to include international training in the education of their future citizens, since many of them will be involved in programs that will impact other cultures. Yet the advantage may not be valued by nations for whom education struggles to provide primary schooling for its youth. Those newer nations striving to inculcate their youth in a national culture may fail to appreciate the usefulness of spending time and money on other cultures, especially when they have inherited curricula oriented toward the values of other, specifically European, cultures. Finally, ethnically heterogeneous nations may well conclude that it is crucially important to emphasize interethnic education (i.e., multicultural education) rather than with the world as a whole.

Intercultural education is a valuable application of anthropology. Yet as with many other attempts to improve humanity’s outlook on the human condition around the world, it faces many challenges.

— John D. Rhoades

INTERNATIONAL ORGANIZATIONS

When the United States decided to reverse the Iraqi invasion of Kuwait, it did not act unilaterally. It turned to the United Nations Security Council.

When the Security Council sought to learn the extent of chemical, biological, and nuclear arms in Iraq, it did not rely on U.S. forces. It dispatched inspectors from the International Atomic Energy Agency (IAEA).

When the international community sought to maintain the suspension of combat in Bosnia, it did not rely only on national efforts. It sent in peacekeeping units under the aegis of the U.N. and the North Atlantic Treaty Organization (NATO).

When states liberalized trade in services and strengthened intellectual property protection in the Uruguay Round, they were not content to draft rules. They created the World Trade Organization (WTO) and a highly institutionalized dispute settlement mechanism.

Formal international organizations (IOs) are prominent participants in many critical episodes in international politics. Examples in addition to those above include the following: Security Council sanctions on Libya, IAEA inspectors in North Korea, UN peacekeepers in the Middle East, and so forth. The U.N. secretary-general’s 1992 Agenda for Peace sets out an even broader range of current and proposed U.N. functions in situations of international conflict: fact finding, early warning, and preventive deployment; mediation, adjudication, and other forms of dispute resolution; peacekeeping; sanctions and military force; impartial humanitarian assistance; and postconflict

rebuilding. But IO influence is not confined to dramatic interventions like these. On an ongoing basis, formal organizations help manage many significant areas of interstate relations, from global health policy (the WHO) to European security (OSCE and NATO) to international monetary policy (IMF). What is more, participation in such organizations appears to reduce the likelihood of violent conflict among member states.

International Nongovernmental Organizations

Much recent scholarship analyzes global structures and processes as a distinct level of social reality. The world is more than networks or systems of economic and political interaction and exchange; it has become a single international society, or world polity.

INGOs have proliferated spectacularly, from about 200 active organizations in 1900 to about 800 in 1930, to over 2,000 in 1960 and nearly 4,000 in 1980, but little systematic attention has been given to this domain of global organization. Unlike states, INGOs lack the rational-legal authority to make or enforce law. Unlike global corporations, they have few economic resources.

Since 1850 more than 35,000 private, not-for-profit organizations with an international focus have debuted on the world stage. Associations, societies, foundations, unions, committees, clubs, leagues, conferences, groups, federations, conventions—the range of designations is extraordinary. They include the Pan American Association of Ophthalmology, the International Exhibitions Bureau, the Commission for the Geological Map of the World, the International Catholic Child Bureau, the International Tin Council, and the International Tug of War International Federation. Most are highly specialized, drawing members worldwide from a particular occupation, technical field, branch of knowledge, industry, hobby, or sport, to promote and regulate their respective areas of concern. Only a few, such as the Scout movement, the International Olympic Committee, the International Red Cross, and the World Wildlife Fund, are widely known.

Universalism

Humans everywhere are seen as having similar needs and desires. They are capable of acting in accordance

with common principles of authority and action, and they share common goals. In short, human nature, agency, and purpose are universal, and this universality underlies the many variations in actual social forms. Most INGOs are quite explicit about this: any interested person can become an active member, and everyone everywhere is a potential beneficiary of INGO activity.

Universalism is evident also in the breadth of INGOs' claims about what they do. Physics and pharmacology are presumed to be valid everywhere. Techniques for playing better chess are not country specific. Red Cross aid will alleviate suffering in Africa as well as Asia. Across every sector, the purposes and means of action promoted by INGOs are assumed to be useful and meaningful right around the world.

Most INGOs adopt a purer form of universalism that stresses the fundamental uniformity of all human actors. Scientific, technical, professional, medical, and business-related INGOs rarely allow much room for particularism, and they account for the great majority of all INGOs.

INGOs are embodiments of universalism, individualism, rational voluntaristic authority, progress, and world citizenship. Decentralized world authority among states both facilitates transnational organizing, because centralized barriers to rational voluntarism are weak and forces transnational organizations to focus their attention on states. In mobilizing around and elaborating world-culture principles, INGOs lobby and harangue states to act on those principles.

The Framework for Inquiry

Decision making in international organizations occurs within a context comprising the functions, the institutional framework and basic procedures, and the historical development of the agency.

Given the nature of the international system, the creation of an international organization requires concrete action by states. Usually, although not always, such actions are consecrated in a treaty. In any case, understanding must be achieved about what is to be done and how.

International organizations have been set up to perform a variety of tasks: keeping the peace, promoting economic development, allocating the radio frequency spectrum, reducing obstacles to trade, ensuring that technology is used only for peaceful

purposes, and facilitating the maintenance of stable exchange rates to name only a few.

In order to describe how decisions are usually arrived at in a particular international organization, it will be useful to classify the actors involved, to consider the ways in which they may exercise influence, and to list the modes of decision making that may be employed.

The actors in international organizations may be classified according to the following categories: representatives of national governments; representatives of and international private associations; the executive heads of organizations; high officials and other members of the bureaucracy of each organization; individuals who serve in their own capacity formally or informally as advisers; representatives of other international organizations, and employees of the mass media.

Of course, not all of these classes of actors will be active in all organizations. For each category of decisions, however, the actors will fall into one or more of these classes, and it is important to know which of these categories of actors typically have the most influence on the outcome.

Thinking About the Future of the International Organization System

In order to think about the United Nations, we must escape the narrow perspectives of daily press coverage as well as the mainstream of the scholarly agenda. Harlan Cleveland believes that the study and teaching about international relations is usually hung up on what's wrong with the picture: riots and their suppression, military takeovers, drug traffic, corporate raids, financial psychoses, arms races, wars, and rumors of wars. If you stand back and look at the whole scene, you see all kinds of international systems and arrangements that are working fairly well. For example: Weather forecasting: World Weather Watch (WMO); eradication of infectious diseases (WHO); international civil aviation (ICAO); allocation of the frequency spectrum (ITU); globalization of information flows; agricultural research for development; U.N. peacekeeping and peacemaking; ozone treaty; cooperation in outer space; law of the sea; the U.N. high commissioner for refugees; the Antarctic treaty.

The stage on which the drafters of the U.N. Charter performed was built during a long historical process, at least 500 years, through which human inquisitiveness, restlessness, and acquisitiveness produced ever-increasing contacts among human settlements,

across even longer distances. The results of this historical process presented opportunities at San Francisco that had evolved out of a growing experience in peaceful cooperation among peoples. But there were also constraints produced by tendencies toward wars of increasing geographic scope with weapons of rapidly increasing destructive power.

If we look back in time from San Francisco, we readily see that the U.N. is a child of the League of Nations. It incorporates important institutional developments of the league, such as an international secretariat and the growth in importance of economic and social activities during the relatively brief history of the league. The U.N. Charter also reflects efforts to gain from the league's failures, as in procedures for deployment of military forces by the Security Council in response to aggression.

Nor was the league wholly a product of its founding conference, the Paris Peace Conference of 1919. The century bounded by the Congress of Vienna (1815) and the outbreak of World War I (1914) was the era of preparation for international organization. The league evolved out of the Concert of Europe created by the Congress of Vienna, convoked to create a new Europe out of the ruins of the Napoleonic Wars.

Humanity was placed on an irreversible path toward the league and the U.N. even earlier than 1815, in the late 15th century, when Europeans began a pattern of worldwide exploration that eventually led to extensive empires in Africa, Asia, and Latin America and to Western domination of the world. Europe-based empires eventually led to the creation of a worldwide system of states. In its early years, the U.N. was deeply involved in the creation of independent states out of former colonial empires.

In developing a historical perspective, it is worth remembering the depiction of the century between 1815 and 1914 as the era of preparation for international organization. How should we characterize the period between the founding of the League of Nations (1920) and today? Very apt would be the era of preparation for global governance. What have the pioneers in this first era of global organizations left as their heritage? They have achieved universality; they have created a network of global organizations responsive to a growing agenda of global problems; they have established a continuous, worldwide presence of this system of organizations, in at least 134 cities in all continents; they have made multilateral decision making commonplace and have developed new procedures for

achieving consensus; they have greatly increased the number of tools available for peace building; they have achieved and made substantial progress in multilateral definitions of a set of fundamental global values, such as peace, human rights, development, and ecological balance; they have made progress in breaking down barriers between the people of the world and global governmental organizations.

Overall we can conclude that there is much more potential for moving forward from this era of preparation for global governance than either the daily headlines or the mainstream of international relations research and teaching recognize. Supportive of possible greater employment of this potential are the vitality of INGO and NGO involvement in the U.N. system and the large number of creative proposals coming from outside the U.N. system. Employment of this potential could move more rapidly if governments of states were able to perceive more clearly the long-term interests and needs of their people. This, in turn, might be facilitated by broader media coverage of the U.N. system, as well as scholarship that offered more probing analysis for human betterment.

Inuit is the term used to identify the indigenous peoples of the Canadian Arctic. Inuit (singular, *Inuk*) means “people” in Inuktitut, Innuinaqtun, and Inuvialuktun, the three dialects of the Canadian High Arctic. The term has replaced “Eskimo” in most political discourse. Eskimo is an external label, long believed to have its origins as an Algonquian Indian word thought to mean “raw-meat eater.”

Despite the narrow meaning of Inuit as a designate for Canadian Arctic indigenous peoples, the term has sometimes been more broadly applied to other Arctic peoples who share their origins with Canadian Inuit. These peoples all speak languages from the Eskimo branch of the Eskimo-Aleut family and include Kalaalit (in Greenland), Inuvialuit (Western Canada), Iñupiat (in Alaska), Central Yup’ik (Alaska), Siberian Yup’ik (Alaska and Russia), and Asiatic Eskimo (Russia). These are all peoples who, like Canadian Inuit, find “Eskimo” an unsatisfactory referent but also prefer to use their own self-designates instead of “Inuit.”

Deciding on appropriate labels for particular groups can be somewhat hazardous, especially since categories and labels can change rapidly as indigenous peoples acquire greater self-determination and autonomy and develop regional, national, and international identities. Anthropologists are quite aware of these shifting sands but continue to use “Eskimo” as an appropriate referent in historical and comparative work.

Canadian Inuit, the subject of this entry, have been attractive subjects for southerners because of their ability to survive in an especially difficult and inhospitable environment, and to do so with a particular style and grace. Their ability to survive is based on a toolkit known for its technical complexity despite very limited materials for constructing that toolkit. The toggling harpoon head, for example, makes ideal use of scarce materials, conserves those materials for reuse, and also ensures the capture of marine mammals that might otherwise escape. As another example, Inuit clothing design and manufacture makes ideal use of furs and skins in a manner that conserves heat without restricting movement or blood flow.

Inuit technical sophistication has translated to the contemporary arena as well. Every anthropologist who has traveled with Inuit has firsthand knowledge

of the ability, honed by experience, experimentation, and necessity, to make equipment repairs with limited and seemingly unsuitable materials.

Inuit are also highly regarded by southerners for behavioral attributes. Equanimity and even cheerfulness in trying circumstances is highly prized by Inuit, and a particular point of emphasis in Inuit culture is the high value placed on helpfulness. Inuit gain greater prestige through giving gifts of food, sharing labor, and the exchange of knowledge than they ever could by being a great hunter or seamstress alone.

Because of the harsh environment in which Inuit live and the sophisticated technology they use to survive in that environment, they were natural subjects for anthropologists interested in understanding human–environment relationships. The Arctic during the 1950s and 1960s became one of the principal testing grounds for the cultural ecology approach developed by Julian Steward.

David Damas's *Environment, History, and Central Eskimo Society*, published in 1969, exemplifies this kind of work. Damas examined the three Central Eskimo groups, Copper, Netsilik, and Iglulik, paying particular attention to the relationships between ecological factors, subsistence patterns, and social features of each of these groups. Although they all shared a common and recent ancestry, some particular social formations, such as the large winter villages that typically contained up to 50 and occasionally up to 200 people, were present or absent in these groups due to ecological circumstances. The method of hunting ringed seals through the sea ice, most commonly found among Netsilik and Copper Eskimos but absent among Iglulik Eskimos, is most successfully accomplished by large groups of hunters working cooperatively. Damas did not discount other, purely social factors that could promote large seasonal aggregations, but most anthropologists assume that the need for food outweighs concerns about sociality.

Although Damas's work, like much of the scholarship of the period, generated a new understanding of Inuit culture, research was also speaking to an anthropological audience increasingly interested in cultural evolution. Inuit, whose subsistence mode is one of hunting and gathering, were at the time widely believed to be living fossils, representatives of how all humans lived during the Late Pleistocene. Based on this belief that Inuit were representatives of the

natural human state, many anthropologists thought that Inuit were important subjects of study on these grounds alone. In addition, the intensification of contacts with the Canadian state raised concerns about the cultural survival of Inuit, providing further impetus for the conduct of anthropological research.

Eventually, scholars realized that Inuit, by virtue of the qualities that made them so attractive to researchers in the first place, were not living fossils, but were contemporary humans who happened to make their living as foragers. Concerns about vanishing hunter-gatherers, however, encouraged another research interest for anthropologists: principles of culture change, acculturation, and cultural survival in the face of colonization by and integration into more powerful societies.

Even as anthropologists were taking a keen interest in subsistence, ecology, and technology, it was apparent that Inuit culture was changing. Before 1950, Inuit relations with the Canadian state were accomplished through the trinity of the Hudson's Bay Company, Anglican missionaries, and the Royal Canadian Mounted Police. All of these groups echoed Canadian government policy and encouraged Inuit to pursue a seasonally nomadic lifestyle centered on subsistence hunting and trapping furs for trade. By the 1950s, however, many Inuit were expressing a preference for living in permanent communities and pursuing wage labor opportunities. The Canadian government, which began to take a more active role in Northern administration during this time, likewise began to encourage settlement.

Settlement was not without consequences. The wage labor opportunities available in new and expanding communities altered some Inuit cultural patterns. In Copper and Netsilik Eskimo communities, for example, the traditional, formal seal-sharing partnerships quickly vanished as hunters adopted new methods and strategies for hunting ringed seals. The introduction of formal day schooling in communities provided a vehicle for the transmission of southern cultural values, and these foreign values were, by 1970, being transmitted to many more Inuit children. The social safety net provided through settlement living resulted in a baby boom during the 1960s, generating a cohort of Inuit raised in the context of settlement life and socialized by a combination of schooling, their own age mates, and, by the early 1980s, television and southern mass media.

Some anthropologists have seen the constellation of changes surrounding settlement as the beginning of the end of Inuit culture, and not without reason. Inuit have experienced the Industrial Revolution in a span of three or fewer generations. Many researchers have documented the problems of alcohol consumption, interpersonal violence, underemployment, and young people's declining involvement in subsistence activities. These problems are commonly interpreted as both evidence of cultural decline and the result of a basic transformation of Inuit social life.

Other anthropologists have remained focused on subsistence, technology, and social organization, examining the changes wrought by settlement and new technological inputs through the lens of adaptation rather than acculturation. William Kemp, for example, working in Lake Harbour, on Baffin Island, during the late 1960s, examined the effects of imported technology on Inuit cultural patterns. Kemp noted that Inuit in Lake Harbour quickly adopted snowmobiles as the principal mode of travel, displacing dogs, despite the significant drawbacks associated with snowmobiles. Snowmobiles are loud, break down frequently under arctic traveling conditions, and require constant feeding with expensive gasoline and oil. Despite these problems, Lake Harbour Inuit felt that the advantages of living in a permanent settlement, which included access to wage labor and access to a larger number of kin, outweighed the disadvantages. Indeed, the snowmobile was what made living in the settlement possible, as it allowed for easier and quicker access to more distant hunting areas.

In this regard, then, the changes wrought by contact and settlement were not driven solely by changes introduced by the Canadian state. Inuit were making choices about settlement and subsistence strategy in reference to their own cultural preferences.

One consequence of greater integration into the Canadian state was the emergence of political movements that sought to protect native rights and formally define the relationships between native peoples and the state. These concerns emerged during the 1960s and early 1970s, as the pace of oil, gas, and mineral exploration in the North increased. These were serious issues. The political relationship between Canada and Inuit had never been resolved via treaty. Land claims movements sought to settle this issue, with the hoped-for result being greater political autonomy and improved social welfare for Inuit.

Beginning in 1975, with the signing of the James Bay and Northern Quebec Agreement, these relationships began to take shape. James Bay was followed by the Northeast Quebec Agreement, in 1978; the Inuvialuit Final Agreement, settling claims in the Western Arctic, in 1984; the Nunavut Land Claims Agreement, settling claims in the Eastern Arctic, in 1993; and the Labrador Inuit Land Claims Agreement, signed in 2003. All of these agreements settled land claims and specified economic, political, and social obligations between Inuit and the Canadian government.

A significant change in the nature of anthropological research paralleled the land claims process. Just as Inuit began taking an interest in their political and economic relationship with the federal government, so did anthropologists. Research on the politics of resource management led to new insights about Inuit resource use and ecological knowledge and led to recommendations about appropriate political arrangements for the comanagement of renewable resources. Investigations of Inuit subsistence practices began to focus on the continued economic importance of subsistence hunting to predominately Inuit communities, where wage labor jobs remain scarce and most Inuit are underemployed or cannot find work. Other examinations of Inuit cultural identity have yielded an improved understanding of Inuit identity formation and the ideology behind Inuit engagement in traditional activities despite external social and economic forces that seek to undermine the viability of those traditional practices.

The net result of this shift in focus has been an anthropology of the North that, as anthropologists such as Asen Balikci and George Wenzel, among others, have noted, is less engaged with theoretical trends in anthropology as a whole. Research in the North is, however, more engaged with Inuit social, economic, and political needs and goals than at any point in time. Research on contemporary Inuit subsistence practices may no longer be speaking directly to theoretical concerns in ecological anthropology, for example, but it is seeking to serve the practical needs of Inuit who continue to derive their continued well-being from hunting, trapping, and fishing.

 IRON AGE

The Iron Age is the final period of European prehistory. The beginning of the European Iron Age is conventionally defined as the date when iron replaced bronze for the manufacture of weapons and tools in the early 1st millennium BCE. In many parts of Central and Western Europe, the Iron Age ends when these regions are incorporated into the Roman Empire in the 1st century BCE and the 1st century CE. In the regions that were never conquered by the Romans, such as Germany, Scandinavia, and Poland, the period from 1 CE through 400 CE is termed the “Roman Iron Age.” In Scandinavia, the period from 400 to 800 CE is referred to as the “Germanic Iron Age,” and the Iron Age ends with the beginning of the Viking period around 800 CE. For most of Central and Western Europe, however, the Iron Age begins around 800 BCE and ends around 1 BCE. Since the later 19th century, the European Iron Age has been divided into an early period known as the Hallstatt Period (ca. 800–480 BCE) and a later period known as the La Tène Period (ca. 480–1 BCE). The Iron Age is important archaeologically because it is the period in which the earliest towns and cities appear in Europe north of the Alps.

Iron Technology

While the copper and tin ores that were needed to produce bronze were derived from a small number of ore sources, iron ore was widespread throughout Europe. The ubiquity of iron ores may have encouraged the

replacement of bronze with iron. Iron objects do not become common in Greece until about 1000 BCE. Iron objects appear throughout Central Europe at about 800 BCE. Although a small number of small iron objects appear in Late Bronze Age contexts in Central and Eastern Europe, these objects may have been produced as a by-product of bronze working. Iron objects appear at a somewhat later date in Northern and Western Europe. Iron working appears in Ireland around 700 BCE and in Scandinavia around 500 BCE. Since iron-making technology was widespread in the eastern Mediterranean by about 1200 BCE, it is likely that iron technology spread through Europe as a result of trade and technology transfer.

Archaeological evidence for iron production includes furnaces, forges, slag, iron-working tools, and finished objects. A small number of iron production sites have been excavated in Europe. These sites indicate that smelting, the separation of iron from its ores, and smithing took place in the same locations. Unlike bronze, which was worked by casting in antiquity, ancient iron was worked by forging. In the West, cast iron did not become widespread until the Industrial Revolution. To work the solid iron, the smith reheated it in a forge and then hammered it to remove any remaining slag and to shape the iron into its final form. The iron that was produced in this way was relatively pure and soft. The addition of organic carbon to produce a harder material was difficult to control. Too much carbon produces a brittle steel; not enough produces a soft iron that makes an inferior tool. Early European iron was produced on a relatively small scale and used primarily for weapons and funerary goods.

Iron production changed dramatically in the Late Iron Age. At about 200 BCE, large urban settlements known as *oppida* (see below) appeared in many parts of Europe. Many of these settlements appear to have been engaged in large-scale iron production. For example, the oppidum of Kelheim, in Bavaria, has produced evidence for the mining, smelting, and forging of iron on an industrial scale. Much of this iron may have been traded to the Roman Empire. By the Late Iron Age, iron was used for a wide variety of tools and weapons, including agricultural implements.

The Hallstatt Period

In temperate Europe (Europe north of the Alps), the early Iron Age is known as the Hallstatt period

(ca. 800–480 BCE). This period is named after a site in Austria that produced nearly 1,000 human burials. While iron replaced bronze for tool and weapon production during the early Iron Age, there are many continuities in settlement, subsistence, and technology between the Late Bronze Age and the Early Iron Age in Central Europe.

Substantial cultural changes appear in West Central Europe during the later part of the Hallstatt period. Around 600 BCE, Greeks from what today is Anatolia established trading colonies in the Western Mediterranean. The best known of these colonies was Massalia (modern Marseilles). At about the same time, towns, such as the Heuneberg, in southern Germany, make their first appearance in temperate Europe. Mediterranean luxury items, including Greek pottery, wine, and Etruscan bronze vessels appear at these towns, indicating substantial trade and cultural contact between West Central Europe and the Greek colonies in the West. At the Heuneberg itself, the city walls were rebuilt in a Mediterranean style. The traditional timber-and-earth fortifications were replaced with a wall built of clay bricks set on a stone foundation. The dimensions of the clay bricks match those used in contemporary Greek buildings. Rich burial mounds, known as *fürstengraber*, or “princes’ graves,” also appear at this time. These burials usually include a four-wheeled wagon, as well as Mediterranean luxury items. The largest bronze vessel known from antiquity, the Vix krater, weighing about 208 kg, was recovered from a rich late Hallstatt burial from eastern France. At about 450 BCE, Greek trade patterns changed, and trading towns such as the Heuneberg went out of existence.

The La Tène Period

Around 480 BCE, a new style of artwork appeared in temperate Europe. The art included decorative elements derived from Greek and Etruscan art, such as the Greek palmette, but these elements were highly stylized. The art is also characterized by stylized plant and animal figures and curvilinear ornaments that were designed using a compass. This style of art is known as La Tène, after the type site in Switzerland where a number of richly decorated iron swords and scabbards were discovered in 1854. By the late 19th century, archaeologists recognized that the La Tène style of metalwork was associated with people the ancient Greek and Roman writers described as “Celts.”

Celts were people who lived in many parts of Central and Western Europe during the first millennium BCE. Most spoke Celtic languages, a family of Indo-European languages that include modern Irish, Scots Gaelic, and Breton, as well as many ancient languages. Although the term Celt was widely used by Greek and Roman authors, there is no evidence to suggest that the Celts ever identified themselves as members of a single ethnic group.

Historical sources, including Julius Caesar’s account of the Roman conquest of Gaul, can provide some important information on Celtic social and political organization. The Greek and Roman sources indicate that Celtic societies were highly stratified, including a warrior elite, specialized priests known as *druids*, craft workers, and a large pool of agricultural laborers. Many of the poor farmers were clients of the elite classes. The nobles offered protection and support to the agricultural laborers in return for loyalty, especially in times of war.

While historical sources can provide some insights into late Iron Age social life, archaeology has revealed important information on La Tène settlement patterns, subsistence practices, and technological practices. In particular, archaeological research has revealed an important change in settlement patterns beginning around 200 BCE. At that time, a number of large fortified urban settlements appear across a broad swath of Central Europe, from western France to the Hungarian Plain. These settlements, which cover an area of at least 25 to 30 ha, are known as *oppida*. The oppida are urban centers that seem to have served a number of functions, including centers of long-distance and regional trade, political capitals for individual Celtic tribes, and places of refuge in times of war. Evidence from Colchester in England suggests that some of these sites may also have served as residences for members of the landed nobility. The excavations conducted at several of the major oppida have revealed important details about the ways the oppida were organized.

Kelheim is located in Bavaria, Germany, at the confluence of the Danube and the Altmühl Rivers, a location that is ideal for trade and commerce. The oppidum at Kelheim, which was occupied from the middle of the 2nd to the middle of the 1st century BCE, covered an area of 600 ha, making it one of the largest oppida in Iron Age Europe. Excavations at Kelheim, including those directed by Peter Wells in the late 1980s and early 1990s, have produced enormous

quantities of smelting and forging debris, including slag, as well as the bases of furnaces that were used in iron smelting. The archaeological evidence from Kelheim clearly indicates that the site's inhabitants were engaged in large-scale iron production. Much of this iron may have been exported to the Roman Empire.

Large-scale excavations have also been carried out at the oppidum of Manching, in Bavaria. Manching is located on the Paar River, and the swampy area near the Paar formed part of the site's defenses. The site was surrounded by a wall 7 km in length, which enclosed an area of about 300 ha. Part of the site was destroyed in the 1930s, when a military airfield was constructed at Manching. A series of excavation campaigns since the 1950s has uncovered about 3% of the Iron Age settlement. The site served as a major center for trade and exchange, and crafts produced at Manching included glass, iron, bronze, and pottery. The center part of the site appears to have been densely occupied; shops, homes, and warehouses lined the streets. The area near the walls was less intensively settled. Many of the oppida east of the Rhine, including Manching and Kelheim, were abandoned in the middle of the 1st century BCE. The reasons for this are not entirely clear, but they remain a focus of research. Regardless of the reasons for their abandonment, the oppida represent the first cities of temperate Europe.

IROQUOIAN NATIONS, NORTHERN

The Iroquoians are a group of linguistically related Native American nations that occupied portions of eastern North America for over a century before contact with Europeans. In addition to their language similarities, Iroquoians in the northeast region of the continent utilized similar technologies and followed similar settlement patterns and subsistence strategies, particularly prior to first contact with Europeans circa AD 1600. The Northern Iroquoian peoples include the Huron and Petun, who at the time of first contact with Europeans occupied portions of present-day Ontario; the Erie, Wenro, and Neutral, who occupied the Niagara Frontier; the Seneca, Cayuga, Onondaga, Oneida, and Mohawk (the members of the Haudenosaunee Confederacy), who occupied much of present-day New York State; and the Susquehannock, who occupied areas in what today is Pennsylvania and southern New York State. Other Iroquoian nations, including the Tuscarora, occupied areas in present-day North and South Carolina. The Tuscarora migrated north during the early 18th century and lived among the Oneida until they were adopted by the Haudenosaunee Confederacy.

Origins

Differences between Iroquoian artifact assemblages and those of the earlier Owasco cultures of the Northeast led archaeologists to initially hypothesize that Iroquoians migrated into the regions they held at the time of contact. This long-held position was called into question during the mid-20th century after the analysis of multiple archaeological collections. Focusing the attributes of ceramics recovered from Iroquoian sites, archaeologists identified stylistic similarities between Iroquoian and earlier vessels. This led researchers to suggest that the Iroquoian culture developed in the northeast over several centuries.

Social Structure

Prior to and for a time after contact with European missionaries and explorers, Northern Iroquoian peoples lived in villages composed of multiple longhouses, which were often surrounded by palisades. Each longhouse in a village housed a different clan segment. As a matrilineal and matrilocal society,

Iroquoians traced their kinship through and lived with their mother's family. When an Iroquoian woman married, her husband moved into her family's longhouse. The couple's children would bear the identity of their mother's clan and reside in the longhouse for life unless a male child eventually married. In the event a couple divorced, the husband would leave his wife's familial dwelling and return to his mother's clan's longhouse along with his personal belongings, while his children would remain with their mother's clan.

The division of labor within an Iroquoian village was primarily based on the sex of an individual. Women oversaw the activities within the household, preparing meals and monitoring children. Iroquoian women also managed the fields of a village, from the planting of seeds to the collection of the harvest, made clothing and utilitarian objects such as pots and baskets for their household, and collected wild edible plants in order to supplement the villages' food stores. Iroquoian men were responsible for hunting for or trapping food, traveling to neighboring villages to trade or to negotiate alliances, defending the village against invaders, and invading neighboring villages themselves. Men were also responsible for clearing fields prior to the planting of crops and for building longhouses.

Technology

Iroquoians mastered the art of working with stone, clay, bone, wood, and shell long before European missionaries, traders, and explorers exchanged metal weapons and tools with their Native American allies and contacts. Stone, for instance, provided a strong, durable, and plentiful resource for crafting tools for everyday tasks. Chert and flint variants served as a dependable and durable material from which to make knives, projectile points, hide scrapers, drills, and other general purpose cutting implements. Harder stones were also ground down to make adzes, celts, and axes for woodworking and digging, while softer stone materials such as soapstone were used by Iroquoians to create pipes, containers, and ornamentation such as beads.

Bone was an equally versatile material for Iroquoian craftspeople. From a utilitarian standpoint, bone could be worked into a number of everyday household items that made work easier. Needles for sewing, awls for puncturing hide, and even fishhooks

were created from bone material. Additional items created by Iroquoians using bone as the base material included whistles, beads, combs, and soft hammers for creating edges on stone objects such as projectile points or knives.

Ceramic technology, originally developed over a thousand years before the development of Iroquoian cultures, provided Iroquoians with another large resource for tool creation and self-expression. At a basic level, an Iroquoian potter could create a variety of cooking and storage containers that varied in size from vessels only inches high and wide to larger pots that were over a foot in diameter. Other items, including both utilitarian and ceremonial objects, were also crafted from clay, including beads and pipes. Stone beads and pipes, while intricate in design, were difficult to create given the density of the base material. Clay, on the other hand, provided an Iroquoian with a material that was easier to shape and decorate.

Vegetation also provided Iroquoians a vast amount of resources from which to craft tools and personal items. A tree alone provided several materials useful to Iroquoian societies, with saplings providing supports for houses and palisades and bark utilized for creating containers. Other objects created by Iroquoians from wood include baskets, spoons, instruments such as flutes, rattles and drums, large mortars and pestles, clubs, snowshoes, spear and arrow shafts, and last, bows. Other vegetation was utilized as well, including corn husks, which were used to make containers and clothing, and gourds, which served as containers and rattles.

After first contact with European explorers and missionaries, Iroquoians gained access to new technologies and materials that often offered a better resource than their traditional technologies did. Metal objects in particular offered an advantage to Iroquoians in that the blades of axes were sharper than those of stone celts, axes, or adzes. Metal pots, while relatively brittle, were still stronger and lighter than their clay predecessors. Furthermore, when a metal object did break, Iroquoians were provided with metal material from which they could fashion their own metal tools and paraphernalia. Shards of a broken metal pot, for example, could be reshaped into items such as knives, spear or arrow points, beads, or other forms of adornment.

Glass beads, one of the more critical trade goods for Europeans, were highly prized by Iroquoians. Having long utilized beads in the creation of ornamentation,

glass beads, created in an array of colors, provided a beautiful and versatile bead that Iroquoians continue to use in the creation of clothing and personal items. However, the wampum that the Haudenosaunee used for ceremonial belts continued to be used even after the introduction of trade beads.

Firearms, one of the most sought-after European objects by Iroquoians and other Native American nations, were also an incredible technology that Iroquoians received from explorers. As with other European goods, the firearms given to the Iroquoians were poorly constructed and constantly needed repair. Initially, Europeans were reluctant to even give Native Americans firearms at all. Inevitably, firearms filtered into Native American societies, replacing the bow in relatively little time.

Trade with Europeans began a decline in the use of traditional Iroquoian technologies, and Iroquoians, like other Native American nations, soon became dependent on European trade goods as fewer Iroquoians were skilled in creating pottery or stone tools. While Iroquoians added their own touches to these newer technologies in time, the traditional technologies that were utilized for centuries were forgotten. Today, Iroquoian men and women have begun relearning traditional technologies and instructing others in ceramic and lithic tool production, providing a reemergence of these long lost skills.

Settlement Patterns

Prior to first contact with Europeans, Northern Iroquoian peoples lived in villages that followed a similar layout. Villages were often located on low lying knolls or hills that provided a measure of protection from invaders. In addition, villages were erected near creeks and rivers so that the populations would have access to fresh water and a supply of fish. Within close range to the village were the fields that the Iroquoians used for growing their crops, the most vital of which were beans, squash, and corn.

The villages themselves were often surrounded by large fences or palisades constructed of saplings gathered from nearby woods, which also provided wood for fires and other structures such as the longhouses that Iroquoians are noted for constructing. As for Iroquoian longhouses, the design and layout of these structures was quite standardized. Constructed by the men of a village, the structures, which were framed with young trees and covered with bark, were built

approximately 20- to 25-feet wide and upwards of a hundred feet in length (longhouses measuring several hundred feet in length were discovered during the excavation of Haudenosaunee sites). A significant amount of partitioning was created within each longhouse in order to provide room for the storage of food and equipment, for the preparation and cooking of meals, and for families to rest and receive protection from either inclement weather or invaders.

For storage purposes, areas were secured at each end of a longhouse. Specific items secured in these areas included weapons, utilitarian objects, crops, and clothing. Fire pits were placed along the central area of a longhouse. In addition to providing heat for the structure and its inhabitants, the fires and the surrounding area provided a space to prepare and cook meals. For the occupants of the longhouse, benches were erected along each wall that served as sleeping platforms and storage areas. Additional posts were placed along the benches demarcating areas approximately 15 feet in width. Each of these areas served as the living quarters of one nuclear family. A couple and their children would eat their meals, sleep within this area, and share a centrally placed fire with a nuclear family on the opposite side of the longhouse. While each nuclear family could utilize the storage areas at each end of the longhouse, families would also dig out storage pits within their area of the longhouse or store personal items on or under the benches.

The length of time a village would have been occupied for was dependent upon a number of factors, most of which were connected to the resources surrounding the village. Often utilizing slash-and-burn agricultural techniques, Iroquoians endeavored to increase the productivity of the soil, but eventually the nutrients would be depleted from the soil, decreasing the yield to the extent that the village could not be sufficiently provided for. This fact alone could force a village to move on. In addition, villages utilized a significant amount of wood for the erection of longhouses, the building of palisades, and the fueling of fires for cooking meals and heating longhouses. Once an Iroquoian village had used up a majority of the trees from nearby forests, they would have been better served by relocating to a new area.

Horticulture

While fish and game meat provided an important source of sustenance for Iroquoian peoples, it was

their crops that formed the basis of their diet. In particular, beans, squash, and corn, referred to as the “Three Sisters” by the Haudenosaunee peoples, provided a major supply of food that allowed Iroquoian societies to live in a village year round. Corn, the most critical of these crops, was used to make soups, stews, and bread, a considerable portion of an Iroquoian’s yearly diet, to which was often added meat and other vegetables. As for the planting and harvesting of crops, Iroquoians worked through a rigorous process to obtain their food staples. Men worked to clear fields for their respective families. After following slash-and-burn techniques, women planted seeds and monitored the fields daily. As the respective plants ripened, women gathered the crops and stored them in areas set aside for food in their longhouse. Meals were then prepared by women for their families and clans.

Political Structure

Northern Iroquoian nations were politically structured around chiefs, each of whom represented a different clan within a village. When chiefs came together to discuss issues such as land use, resource allocation, and conflict, they would all participate in deciding what course a village (or entire confederacy) should take. However, each of the chiefs was present to voice the views of their entire clan, not solely their own individual beliefs. Given the matrilineal structure of Iroquoian societies, chiefs were often installed by the elder mothers of each clan. Failure to follow the directives of the clan, or particularly the clan mother, could result in the removal of the chief, whose title was not hereditary.

Conflict

The presence of palisades and the location of prehistoric villages on elevated parcels of land suggest that Iroquoians lived in a conflict-rich environment, a point reiterated by the history of the Haudenosaunee Confederacy’s creation. According to that history, the Iroquoian nations throughout the Northeast were continually fighting one another. Hiawatha, an Iroquoian man who had lost his family to the long-running hostilities, helped convince the Seneca, Cayuga, Onondaga, Oneida, and Mohawk nations to stop all fighting and become part of a confederacy that would protect and serve them all. Other Iroquoian groups were offered

a chance to join, but they refused that offer. While conflicts did continue to arise among the members of the Haudenosaunee Confederacy, the confederacy did help its member nations to avoid any large-scale outbreaks of war. However, confederacies of Iroquoians existed outside the Haudenosaunee, and there appeared to be a constant amount of discord between these different Iroquoian groups. With the arrival of Europeans during the 17th century, this discord was exacerbated as many Native American nations vied for access to European goods and for control of the resources Europeans wanted.

At the time, beaver felt clothing was extremely popular in Europe, and European explorers were intent upon obtaining as many beaver pelts as possible. To enlist the aid of Native Americans in this endeavor, Europeans provided villages with firearms, glass beads, and metal tools. Iroquoians and other Native American peoples attempted to obtain as much of the European trade goods as possible. Realizing that Europeans could go to any of a number of nearby villages, Iroquoians became embroiled in a large-scale war as the Haudenosaunee peoples in particular began infiltrating the territories of their neighbors to obtain beaver pelts and secure trade relations with the Europeans.

By the mid-17th century, many Iroquoian nations had been eradicated or dispersed by the Haudenosaunee Confederacy, which outlasted its neighbors. Throughout the course of this warfare, many members of the other Iroquoian nations were actually assimilated into different Haudenosaunee nations and adopted by different clans. Other members of the Northern Iroquoian nations fled to non-Iroquoian territories and began residing with native peoples there, where they retained a varying degree of their long-held traditions.

The end of this war opened up vast territories for the Haudenosaunee confederacy and gave them a prominent role in trade with Europeans. However, the Haudenosaunee members soon became entrenched in other large-scale conflicts that threatened the existence of the confederacy itself as its individual members took different sides in the American Revolution.

The Iroquoians had previously become involved in a struggle between European powers during the French and Indian War. During that event, the Haudenosaunee Confederacy, allied with the British, fought against other native peoples and allowed that conflict to decimate entire villages and nations. The

Haudenosaunee peoples appeared steadfast in not letting that happen once again. When the British and United States of America began fighting, the Haudenosaunee nations held a council and decided that the confederacy's members would not become involved in the revolution. However, individuals from each nation of the Haudenosaunee decided to take action, leading many other Haudenosaunee to take sides. Inevitably, all the nations became involved. The Seneca, Cayuga, Onondaga, and Mohawk nations allied themselves once more with the British, whom they felt had been very supportive of the Haudenosaunee in the past. The Oneida nation and the relative newcomer to the confederacy, the Tuscarora nation, sided with the United States, with whom the Oneida and Tuscarora had established a cooperative coexistence.

Throughout the war, the Haudenosaunee often proved to be a considerable force to be reckoned with, regardless of which Haudenosaunee nation it was. Whenever an engagement occurred with Haudenosaunee fighters on both sides, however, the Haudenosaunee fighters would not participate. During the course of the revolution, retaliatory strikes from both the United States and Britain destroyed many of the Haudenosaunee villages scattered throughout the Northeast, leaving hundreds of Native Americans without food or shelter. At the end of the revolution, the nations that sided with Britain were forced to reside on land set aside by the United States in the present-day region of Buffalo, New York, and other western and northern New York localities. The Oneida and Tuscarora peoples, however, were allowed to retain their long-held territories. Eventually, even they were forced west as more Euro-Americans began to settle in central New York state.

The Haudenosaunee peoples, being the only substantial Northern Iroquoian confederacy remaining by the end of the American Revolution, became entangled in other conflicts as time wore on. Much of the conflict entailed military action as members of the Haudenosaunee supported the United States in the War of 1812, the American Civil War, World War I, World War II, the Korean War, and the Vietnam War. In each instance, Iroquoians served with distinction and reflected a tradition of bravery and self-sacrifice. However, other conflicts, void of intense military action, confronted the Iroquoians who remained.

After the American Revolution, the Iroquoian peoples still in the New York region were forced onto

small tracts of land that became increasingly smaller as American citizens and local governments purchased acres of reservation territory through questionable land sales that left the Iroquoians little land on which to survive as they had prior to contact with Europeans. Their struggle to survive was arduous as Iroquoian women and men found new areas of employment that would enable them to provide food, clothing, and shelter for their families. Many Iroquoians eventually left the shrinking reservations to pursue opportunities in cities and towns across the United States. For those who remained in western New York, opportunities opened as a tourist environment developed around Niagara Falls, where Iroquoian women created and sold bead-decorated moccasins, purses, wallets, and hats. Other Iroquoians looked for work as servants or general laborers. By the early 20th century, Iroquoians, particularly Mohawk Iroquoians living in Canada and the United States, worked as construction workers and were critical to the erection of early skyscrapers that still dominate the skyline of major urban centers throughout northeastern North America. All the while, many of the surviving Iroquoians continued to maintain traditional beliefs when possible. The efforts of Iroquoians to combat time and outside influence on traditional beliefs have been successful in that many Iroquoians today remain aware of their heritage and actively reach out to teach other Iroquoians and non-Iroquoians. Members of the Haudenosaunee Confederacy in particular continue to fight for their lands and rights, only they do so in courts and capitol chambers throughout the world as opposed to battlefields. Speaking out for human and the rights of indigenous peoples on a world stage, they continue to prove their resolve and determination.

History

While multiple Iroquoian nations existed at the time of contact with Europeans, few survived as distinct nations after the warfare that ensued as Native American peoples throughout the continent competed for access to European trade goods, the most sought after being firearms, metal tools, trade beads, and alcohol. European diseases introduced through missionaries and explorers had an equally devastating effect on the indigenous populations of North America, including the Iroquoians. Consequently, few records of some Northern Iroquoian peoples exist

to inform us about their unique histories, even as other Iroquoian peoples left an extensive impression in the annals of history.

Haudenosaunee Confederacy

The Haudenosaunee Confederacy has long held a prominent position among Native American entities. The Seneca, Cayuga, Onondaga, Oneida, Mohawk, and Tuscarora long occupied many regions of present-day New York state. Before the arrival of Europeans, the people of the Haudenosaunee Confederacy, commonly referred to as the “Iroquois,” maintained a strong regional presence that protected its members from both internal and external interference. As Europeans began entering North America and introducing their wares to various trade routes, the Haudenosaunee maneuvered to control access to the European goods and the beaver pelts and other resources that Europeans were most interested in. Inevitably, the Haudenosaunee were successful in defeating and dispersing neighboring Northern Iroquoian peoples. As mentioned earlier, the Haudenosaunee maintained a strong presence in the Northeast and a strong relationship with the British. After the American Revolution, the Haudenosaunee were forced from their traditional homeland to the western portions of New York state as well as a few areas in central and northern New York state. British officers, in recognition of the service the Senecas, Cayugas, Onondagas, and Mohawks had given, secured lands along the Grand River for the Haudenosaunee, which became the Six Nations Reservation.

Over the next 50 years, the Haudenosaunee lost hundreds of acres of land to questionable land deals. Faced with little land to farm and a loss of important hunting grounds, the members of the Haudenosaunee were forced to search for alternative ways of securing food and supplies. This need led many to work off of reservations in jobs that included service in the United States military, as maids or housekeepers, or as general laborers.

Throughout the 19th and 20th centuries, the Haudenosaunee were confronted with obstacles that tore away at the fabric of their traditions. Haudenosaunee children were placed in schools that strove to purge students of their native language and traditions, the United States seized thousands of acres of Seneca and Tuscarora land in order to build the Kinzua Dam in Pennsylvania and a reservoir in Niagara Falls, and more and more of the Haudenosaunee left the reservations

in search of employment and opportunity. Through it all, individuals among the Haudenosaunee nations have endeavored to reinforce the traditional teachings and beliefs of the confederacy. Members of the Haudenosaunee also started to seek protection for indigenous peoples through the establishment of organizations such as the Indian Defense League of America. During the latter half of the 20th century and into the 21st, the Haudenosaunee revisited treaties their ancestors made with the United States, and they are reclaiming some of the land and resources they lost long ago.

Huron Confederacy

The Huron, a confederacy of Iroquoian nations that occupied regions of present-day Ontario, were an adversary of the Haudenosaunee. The Huron allied themselves with the French after contact and had established a significant trade network. Positioned near multiple sources of trade and fur, the Huron became a target of increasing Haudenosaunee attacks during the mid-17th century. The nations of the Huron confederacy, crippled by European diseases and constant conflict with the Haudenosaunee nations, were dispersed, with many individuals being adopted into other Iroquoian nations, including those of the Haudenosaunee confederacy. Huron peoples continue to live in Canada today on land set aside by the Canadian government.

Erie, Wenro, and Neutral Confederacies

The Erie-, Wenro-, and Neutral-occupied areas of the Niagara frontier, including much of the present-day Buffalo metropolitan region. Each was a confederacy of nations that spoke an Iroquoian language and were either dispersed, adopted, or destroyed by Haudenosaunee during campaigns during the mid-17th century. The Wenro, closest in location to the Seneca nation, were the first of the three to react to growing hostilities. After moving north to Huron territories, the Wenro were dispersed when the Huron villages were attacked. The Neutral, who were named so for long maintaining good relations with both the Huron and Haudenosaunee, eventually became the target of the Haudenosaunee and were dispersed. The Erie likewise found themselves the enemy of the Haudenosaunee and were dispersed during the 1650s. While many of each group perished during their respective conflicts,

more were assimilated into Haudenosaunee nations or into other native nations as well.

possibly being the true founders of North American democracy. They developed a code of honor and established a social and political system, which proved to strengthen their forces and connect their nations. Iroquois women elected chiefs, who played key roles in war, economy, and culture.

The Iroquois inhabited the areas now known as New York State, southern Ontario, and the St. Lawrence region. They were first comprised of five nations that came together to form a union. These nations include the Mohawks, Oneidas, Onondagas, Cayugas, and Senecas. Between the 14th and 16th centuries, these tribes formed the Iroquois League of Five Nations, founded by Tadodaho and Hiawatha, although Iroquois themselves say the league is 1,000 years old. The purpose of the league was to establish peace among the tribes and to provide protection and a strong defense from attack by others. Around 1815, the Five Nations later adopted another nation, the Tuscarora, forming the complete Iroquois Six Nations Confederacy.

The Mohawk Nations found in New York are located on the Akwesasne Reservation, Ganiengh, and Kanatsiohareke. In Canada, Mohawk Nations are found in Kahnawake, Kanesatake (Oka), Akwesasne, Tyendinaga, and Gibson. Oneidas Nations are found in Oneida, New York, and Oneida, Ontario. Onondagas Nations are found in Onondagas, New York. The Seneca-Cayuga Nation is found in Oklahoma. Seneca Nations in New York are located in Tonawanda, Allegany, and Cattaraugus. All six nations are found on the Six Nation Reserve in Ontario.

Spirituality and Healing

The Creator is known as the Great Spirit who created the physical world and rules celestial and human beings. Traditional teachings of how the world was created center around the Skywoman, named Aientsik, a descendent from the heavens, who was the first to walk on the earth. Aientsik gave birth to a daughter named Tekawerahkwa. Tekawerahkwa gave birth to twins, Tawiskaron and Okwiraseh. Tawiskaron was a jealous sibling who could not live up to the magnificence of his brother. He created elements within the natural world, including raging rivers, rapids, and vicious animals. His brother Okwiraseh created all that is pure and beautiful. The legend continues to explain that when the two met in battle, Okwiraseh defeated his brother Tawiskaron. As a result of his

The Iroquois, or *Houdounausee* (People of the Longhouse), are an important nation of Native Americans who made significant contributions in molding North America. Their social and political systems as well as their way of life strongly influenced the way North Americans live today. They have been characterized as relentless warriors in addition to

defeat, Tawiskaron was confined to the dark areas of the world and governs the night, including all of the destructive creatures.

Messengers from the spirit world explained and demonstrated techniques in which the Iroquois people were able to properly honor and give thanks to the Creator. They shared moral teachings and specific rituals that formed the basis of religious practices and beliefs. Music and dance were included in ceremonies and were believed to be a means of preserving the human–earth relationship. As time went by, the teachings faded, and the Iroquois became a fearful and violent people. When suffering and hopelessness were felt by most Iroquois people, a prophet was sent from the Creator. His name was Skennenrahawi, also known as “the Peacemaker.” The purpose of the Peacemaker was to restore hope, heart, and happiness among the Iroquois. He was to create peace among the Iroquois tribes and reform their way of life by creating a League of Iroquois nations, which would be strengthened by their unity. As the Peacemaker traveled from village to village, he brought with him a set of rules known as the “Great Laws of Peace,” which were meant to be guidelines for all Iroquois. Skennenrahawi met a woman named Jikonsasay, who helped spread his teachings. Because Jikonsasay played a vital role in reaching a number of Iroquois, Skennenrahawi decided that women should be involved in the social and political decisions within the clans. Therefore, it was decided that not only would women openly participate socially and politically within their communities, but they would also choose which male leaders would be appropriate as clan leaders. Another individual often referred to as one of the Peacemaker’s second disciples was a man named Aiionwatha, also known as Hiawatha. Aiionwatha was skilled in articulating the Peacemaker’s messages by creating powerful prayers. He also found productive ways in which to physically express the messages to the Iroquois nations. The Peacemaker, along with his two main disciples, Jikonsasay and Aiionwatha, created peace among five Iroquois Nations, known today as the Grand Council and the Haudenosaunee Confederacy.

A second influential Iroquoian spiritual guide and prophet was identified as a Seneca *sachem* (chief) named Handsome Lake, also known as Ganeodiyo. He was born approximately in 1735, during the most tumultuous days of the Iroquois. The Iroquois were located on small reservations, and their culture was under tremendous stress. Handsome Lake instructed

his people on many teachings given to him by the Creator. He expressed his appreciation of children and their needs as growing individuals. He taught parents that listening was one of the most important skills in child rearing. His purpose was to reform his people into sober, life-appreciating, peaceful, and moral people. He traveled village to village preaching a new way of life, a new doctrine. He had a life-altering near death experience that would continue to shape his existence. Celestial and physical beings were frequently sent by the Great Spirit to give Handsome Lake messages, which he would continue to share with the League. They warned of the evils of temptations to be aware of, which were present in the world and lingering among their communities. He also explained how the world operated in terms of equilibrium. Each member in society possessed a specific talent or characteristic which, when all put together, would create a unified and functioning unit. Many communities embraced the teachings that Handsome Lake spread. He was successful in teaching the means of achieving peaceful and moral communities. Handsome Lake’s teachings across the League’s communities have often been referred to as the movement to a “Temperance Society” or the “New Religion.” He is claimed to have created the Handsome Lake Code, which contains a set of ethics describing the ways in which to live life to the fullest, while respecting family, members of the community, strangers, and the environment. He wished for the survival and harmony for his people and their culture.

There are many forms of healing among Iroquois nations, one of which includes the False Face Society. The False Face Society use a variety of wooden masks, carved from live trees, which have the power to frighten evil spirits that cause illness. With crooked facial features, the masks are often painted red, black, white, or a combination of these colors. The faces represent grandfathers of the Iroquois. The masks aid in reconnecting humans and nature, creating an equilibrium that cures illness.

Other forms of healing involve the use of natural remedies. Some native medicines include quinine, chamomile, and ipecac, in addition to a variety of energy-rich foods. The Iroquois were taught that the Creator gave the inhabitants of the earth all elements needed within the natural world to cure illnesses. They had developed a form of penicillin used to cure infections, which was administered through a syringe. Many medicines and remedies used today

originated from techniques and remedies used by the Iroquois as well as other Native Americans. Dream interpretation was used to as a means of treatment therapy. Finding hidden clues within dreams was a technique used in unraveling causes of illness. Similar to a modern-day psychologist, the dream interpreter would analyze the dreams and determine the appropriate methods to cure the illness. Cleansing the body was a principal component in maintaining good health. Purges, fasts, and specific baths were employed. Cleansing the body was seen as a process in which to detoxify not only the physical body but also the mental and spiritual aspects of the being.

Family

The Iroquois believed that all human beings were created equal and each individual possessed a special gift, talent, or ability. Children were regarded as ultimate blessings and gifts from the Creator. Therefore, children were treated with much respect and taught by all members of the family. Infants were seen as being part of the spirit and the physical world. Children spent a great amount of time with grandparents and elders, learning about the culture, customs, beliefs, and history. The importance of this reflected in a strong sense of attachment to the family and community. Learning through experience was strongly recommended. Many outside observers confused this idea of growth through personal experience and freedom of decision making with a lack of discipline.

Women played an important role within the family and nations. Traditional teachings say women were given the ability to create. Every female birth was a blessing the Creator had given the nation. The lineage would be able to continue to grow and multiply through the birth of each female. From birth, female members were encouraged to take on leadership roles within their families and to freely express themselves. Young girls were trained in planting techniques, food preparation, and preserving. Women's occupations consisted of tilling the fields, dressing the meats and skins obtained by the males within the community, and gathering the fuel needed for the winter's fire.

Male children were taught at a young age the techniques used to protect and provide for the family and clan. Boys were taught specific characteristics and uses of a variety of foods. They were also taught which herbs and plants were used in tradition medicines and cures to illnesses. Survival skills were taught,

including how to use the natural environment to shelter and create warmth and how to read weather patterns to determine what to expect. Hunting, fishing, trapping, and tracking skills were learned. During puberty, a young boy would participate in a vision quest, which would require the boy to survive on his own in Mother Earth, fasting and praying without distraction. He could be visited by an animal, which would represent his spiritual guide. When the boy returned, he would be seen as a young adult.

A *clan* is defined as a group of families who share a common female ancestry. They are named after animals that have a special significance and importance to the tribe. These include the turtle, bear, and wolf among all Iroquois tribes, while the Seneca, Cayuga, and Onondaga have an additional six, which include the crane (heron), snipe, hawk, beaver, eel, and deer. Marriage within the same clan is forbidden. Clan members are referred to as "sisters" and "brothers," and blood relations are not accepted within a marriage. Marriage between a man and a woman represents not only the union of a couple but also a merger between families and clans. The mothers of the couple are asked for permission to marry. Once the marriage is complete, the woman has control over the property. If for some reason, the couple were to separate, the woman would have custody over children and the man would have to leave with only his bare possessions. Iroquois are matrilineal, and children inherit the clan of the mother.

Social and Political Organization

Most Iroquois lived in longhouses, which were constructed by poles and elm bark. Measuring approximately 15 to 30 meters long, the longhouse was divided into separate sections, which would house the extended family. These houses were large enough to accommodate up to 120 people. This family residence was an important element in the survival and strength of the family and culture. All members living in the longhouse contributed to child rearing. Villages were generally permanent, but they moved once the soil had become exhausted, which would take approximately 20 years. Today, most Iroquois live on reservations and no longer reside in the traditional longhouses. Reservations commonly include elements seen in small towns and villages, but Iroquois communities are rich in Iroquois symbols, traditional cornfields, arts-and-crafts stores, and cultural centers.

It was believed that since women were more sensitive to the rhythms of the Mother Earth, they controlled the land in which they lived. Women were in control of all aspects and issues involved within a community. Iroquois social and political systems were controlled and monitored by women. Women were in charge of maintaining and taking care of the crops and seeds of the “three sisters” crop—corn, beans, and squash—well as other crops and medicines.

Males within the community were in charge of clearing the fields, building homes, and providing security and safety. They left in the fall to hunt and spent the spring fishing. Men spent a considerable time preparing and engaging in battle. Most conflicts arose from property and territory disputes. Males, more specifically, fathers and husbands were responsible for maintaining the well-being of their families. They were the protectors within the village and used whatever means possible to uphold their defense.

The League of the Five Iroquois Nations—the Mohawk, Oneida, Onondaga, Cayuga, and Seneca—is believed by some to have been formed around the 15th to 16th century, but Iroquois believe it is older, formed around 1,000 years ago. A sixth member, the Tuscarora, joined at the beginning of the 18th century. The political system within the League included 50 sachems from a variety of clans. There was a set representation of sachems among the different Iroquois tribes. These included 9 from the Mohawk, 9 from the Oneida, 14 from the Onondaga, 10 from the Cayuga, and 8 from the Seneca. Although women were not able to become a sachem, they had the power to choose which male would represent their clan as a sachem. Women also had the right to remove any sachem they felt was not fulfilling his role. Sachems would meet and discuss issues pertaining to the maintenance and development of the Iroquois people. They would debate in a systematic manner, where every sachem would have the opportunity to express their opinion. A consensus between all sachem would render the decision to the issue at hand. During debates, the order in which a sachem voiced his opinion resulted from the tribe he was from. Earlier members of the League, such as the Mohawk, Onondaga, and Seneca, were referred to as “elder brothers” or “uncles” and therefore spoke first during meetings and discussions. The Oneida, Cayuga, and Tuscarora were referred to as “younger brothers” or “nephews.” The League is described as one of the most effective political and social systems

known to North America. Although the Iroquois have been described as a “primitive” group of nations, the organization of the League proves this wrong. The League devised a valuable and systematic set of values and laws that maintained a great amount of order and regulation among the nations. The League was quite successful up until the American Revolution, when a collapse occurred, which devastated the League. The organization of the League and its confederacy is a reflection of current North American democracy and government.

Today, traditional governments continue as they did in the past in Tonawanda, Tuscarora, and Onondaga. Akwesasne and Oneida function with a traditional council of chiefs as well as an elected tribal council. Although each community now has its own separate government, chiefs carry on the tradition of the confederacy, meeting independently from American and Canadian control.

Over the centuries, the Iroquois adapted and changed, through the adoption of agricultural practices, receiving the message of the Peacemaker, and the Handsome Lake cultural revitalization. The Iroquois today believe they are undergoing another cultural revitalization, caused by pressures of globalization and changes in their economy. Iroquois are revitalizing their language and culture through art, dance, literature, and education. They are actively discussing new forms of government, to find balance between elected councils and traditional governments. Iroquois have been international leaders and outspoken activists to protect Mother Earth and promote sustainability through traditional teachings “making decisions for the Seventh Generation.”

IRRIGATION

Rain-fed agriculture, the converse of irrigated agriculture, has traditionally meant cultivation of plants without adding additional water beyond that which falls naturally on them from the sky or flows to them

Source: © iStockphoto/David Freund.

as surface water. Obviously, there is a spectrum of human intervention between minor flood control management and massive irrigation works, as well as a spectrum in scale between typical surface flows and the traditional floods of major river systems. A third spectrum relevant to understanding the role of water in agriculture involves the energy needed for supplying the water to the fields, which ranges from low in some gravity-fed systems to high in systems requiring additional energy inputs for raising water to the level of fields well above the water table.

It is possible that the first crops cultivated by irrigation were small flood control systems on alluvial fans in arid regions, such as Jericho, circa 9000 BC, but it is just as likely that small flood control management works were built along river systems having a natural flood, and it is unlikely we will ever know when or where the earliest such systems were built, since alluvial soils in flood plains are rearranged annually and the likelihood of the earliest such works leaving a trace down to the present are slim. Significant irrigation works in the Middle East date at least to 5000 BC in the Nile, and an early major irrigation project was completed there around 3100 BC during the 1st dynasty.

If we leave unsolved the question of who was first to irrigate, we can concentrate on the broader ramifications of irrigation technology. Modern measuring systems tempt researchers to believe that irrigation is required where less than a particular amount (e.g., 250 mm) of rainfall occurs. Premodern measuring systems were generally more sophisticated and allowed for temperature, orientation to the sun, soil characteristics, temporal distribution of rainfall, and evapo-transpiration by evaluating rain-fed fields not in terms of area and precipitation, but in more direct terms of the optimal amount of seed they would support. Even small gravity-fed watershed-harnessing systems can concentrate rainfall from a larger area onto a smaller one, and nature does a fair job of this in many circumstances. Thus, precipitation requirements for annuals like grains (trees can survive on the water table if it is high enough) make sense only as

guidelines, and the ethnographic literature is full of the expected exceptions (e.g., the Hunza, in Northern Pakistan, who require only 180 mm for rain-fed agriculture).

Karl Wittfogel developed the idea that irrigation works were both the products of centralized states and, via the control possible by monopolizing the water supply, the basis for the development of a particular (oriental) version of state despotism. This theory was taken up by many scholars but is now not seen as fitting well many of the very areas it was thought to explain best, such as Bali, where a strong case has been made that vast irrigation systems were constructed and regulated without any significant role for the state. If it does not have the broad relevance claimed for it by Wittfogel, some scholars, such as Sidky, claim it has explanatory value for 18th-century irrigation among the Hunza. Stanish suggests that part of the argument may be valid if reworked in terms of linking political complexity to labor intensification and declining returns to labor in areas largely under local control.

Because many early civilizations developed in riverain areas and also developed irrigation systems, archaeologists have focused a lot of attention on irrigation. In a classic work, Butzer attributes the repeated elaborations of the irrigation infrastructure in the Nile during dynastic times to local communities rather than to centralized state initiatives but notes the extensive efforts under state control to develop the Faiyum during the Hellenistic period. It may be that this model of early local development usurped only in much later times by a central state will fit far more premodern situations.

Irrigation systems, whose infrastructure is durable, both significantly improve the efficiency of human labor, through the multiplier impact of the infrastructure, and enable more labor to be used effectively in a given unit of area. At some level of effort (the margin in terms of labor efficiency), there begins to be a general trade-off, under *ceteris paribus* conditions, with intensification leading to higher returns per unit area and declining returns per unit of labor. Many irrigated systems pass beyond an optimal point where both returns to labor and to unit area increase and sacrifice the former for the latter. They often operate in this suboptimal area, from the perspective of returns to labor, because the sociopolitical system has prioritized returns to unit of area or water or even some combined unit of land and water.

It is normal in many irrigation-based societies for the labor of many to be constrained in some measure by the will of the few. Varied explanations for how this comes about have been proffered. Inefficient uses of human labor, which are inevitable where the other factors of production (land, water, and capital, understood broadly) are unevenly distributed, may well have reached an early nadir in large-scale irrigation contexts.

The modern era of high-tech dams and irrigation projects has brought to the fore issues of environmental damage; displacement of peoples by new lakes, with a host of associated social and health issues; a regular prioritization of the energetic needs of urban areas over the needs of farmers; and a plethora of opportunities for corruption by elites, companies, and international organizations. Large-scale irrigation projects promise more predictable yields, greater independence from world market fluctuations in crop prices, and local sources of energy. Only in rare cases where the climate and ecology are already optimal for the crops in question do such projects provide crops at competitive world market prices if all costs are considered. Despite typical international advice to the contrary, modern decisions to undertake large-scale irrigation stand or fall on political and social considerations, not economic efficiencies, and would do well to be so understood.

One of the world's major and fastest-growing religions, Islam is practiced by about 1.3 billion adherents throughout the world, about one fifth of the world's population. A monotheistic faith, *Islam* literally means "submission to the will" of God in Arabic, the language of its origin and of its sacred text, the Koran. Islam was founded by Muhammad, a man of 6th-century Arabia, who is considered the "seal" (or last) of the prophets by the community of believers.

Islam was studied by European scholars, including some considered to be among the founders of the discipline of anthropology, as Europe expanded its political and cultural domination of Asia and Africa in the 19th century. Recently, detailed ethnographic studies of the localized practice of Islam have become the main focus of anthropological inquiry.

Basic Practices and Beliefs

Islam is based upon five religious duties, often called the "Five Pillars." The first pillar is the profession or declaration of faith: There is no god but God, and Muhammad is the messenger of God. Recitation of this sentence makes a person a Muslim, one who submits to God. The second duty is prayer five times a day: dawn, noon, midafternoon, sunset, and nightfall. Each prayer is said facing Mecca, in a state of ritual purity, and is composed of a number of bows or prostrations to God. People may pray anywhere, although many congregate at mosques, Muslim houses of worship, especially for the Friday noon prayer.

Almsgiving is the third pillar or religious duty. Generally, most almsgiving is personal and direct from donor to recipient. Historically, in some countries, it has been an obligatory tax on those who were able to pay. The fourth pillar is fasting during the month of repentance and purification, Ramadan. Eating, drinking, smoking, and sexual relations are prohibited between dawn and sunset. At night, communal feasts for family and friends are common. The last pillar is the pilgrimage to Mecca, which must be made at least once in a lifetime if possible. Over a million people annually make the pilgrimage during the month of Dhul-Hijja. Among the many ritual acts the pilgrims complete are seven circumambulations of the Kaaba, a sacred shrine originally consecrated to God by Abraham. Those who make the pilgrimage to Mecca are called *hajjis* and are much respected when they return to their local communities.

A foundational belief in Islam is that God has a unitary nature. God is referred to as omniscient, merciful, compassionate, generous, everlasting, the most high, and the judge. These and other characteristics of God are often part of men's names; for example, *Abdul Rahman*, or "slave of the compassionate," indicates a man's submission to God in his personal name.

The Koran, Islam's holy book, contains 114 chapters, arranged longer to shorter, and contains legal, judicial, and ethical norms. The Koran is considered the last, final, and perfect revelation from God to humankind. It refers many times to the Day of Judgment, when God will judge people and the good will go to paradise and the evil to hell.

Other customs associated with Islam are prohibitions against the use of pork, alcohol, and representations of animate objects. The enforcement of these prohibitions has varied historically and regionally. Although the veiling of women is often linked to Islam, the Koran specifies modest dress, not the complete veil or the seclusion of women.

Historical Development of Islam

Muhammad was born in Mecca, a prosperous town and center of a pagan cult in the Arabian Peninsula, in AD 570. His tribe, the Quraysh, was powerful and wealthy; his family lineage was Hashim, a minor although respected group. His father died before his birth and his mother when he was only 6. At age 40, while meditating in a cave near Mecca, Muhammad received revelations from God via the Angel Gabriel

and began reciting these to the people of Mecca. The Koran, literally “the reciting,” is the collection of these revelations and thus is God’s direct word, according to Muslims. Not only did Muhammad attract followers from among the poor of Mecca, he also threatened the prosperity of the wealthy who gained economically from pilgrims visiting the city’s pagan shrine. Some Meccans began to persecute Muhammad and his followers.

Yathrib, a city north of Mecca later renamed Medina, was in the midst of a series of disputes that Muhammad was asked to arbitrate. Muhammad and his followers migrated to Medina, where they formed a community and state based on ties of faith rather than blood. This event, the Hijra or Emigration in 622, marks the year 1 in the lunar Islamic calendar. After a series of battles with the Meccans, Muhammad and his followers returned to Mecca in triumph. The Kaaba, a large black stone and the shrine, which previously housed idols, was purified and dedicated as the place where Abraham and his son Ishmael worshipped God.

Muhammad died in AD 632, leaving no male heir or successor. However, his daughter Fatima was married to Ali, one of Muhammad’s earliest followers, cousin, and adopted son. Some, known as the Shia (from *shiat Ali*, or the “party of Ali”), thought Ali was Muhammad’s true successor, but a group of Muhammad’s counselors selected Abu Bakr, whom the majority accepted. The dispute about leadership continued through two additional successors, or caliphs. Although Ali finally was selected the fourth successor after Muhammad, he was never universally accepted. After Ali’s assassination, the Shia looked to his eldest son Hasan, but the powerful governor of Syria, Muawiya, threatened his position. Hasan

retired, and the Shia looked to Ali’s second son, Husayn, for leadership. The forces of Husayn and Muawiya’s son, Yazid, battled near Karbala, Iraq, on the 10th of Muharram, the first month of the Islamic calendar, in AD 680. Husayn and many of his family and followers were killed. The Shia commemorate the event each year on the 10th of Muharram in a reenactment of Husayn’s martyrdom.

The orthodox majority of Muslims, 90% of the total, are known as “Sunnis” from the word, *sunna*, Arabic for customary conduct, referring to Muhammad’s own practices. The Shia remain a minority of about 10% or 15%; however, they control the state in Iran and are the majority in Iraq. Shiism has been divided into numerous sects since the 8th century. Most are known as *Imamis*, or “Twelvers,” because they accept 12 *imams*, or leaders, from the first, Ali, to the 12th, who is believed to have hidden himself away only to return later to restore justice before the end of the world. Others include the *Ismailis*, “Seveners,”

who accept a different 7th imam than the Twelvers, the Zaydis who accept a different 5th imam, and many more.

The victory of Yazid over Husayn consolidated the dynasty of caliphs known as the Umayyads (AD 661–750). Islam continued to expand across North Africa and up through Spain as well as through Central Asia, which had been Buddhist, to India and the frontiers of China. Many non-Arab peoples, including Berbers, Turks, and Persians, converted to Islam. The growth of non-Arab peoples within the Muslim community created difficulties in governance, leading to a series of revolts and a new ruling dynasty, the Abbasids, with capitals at Baghdad (AD 750–1258) and Cairo (AD 1261–1517).

In the 12th and 13th centuries, a major shift in popular religious expression took place in the Islamic world with the development of *sufism*, frequently defined as “Islamic mysticism.” The word is derived from the Arabic word for “wool,” *suf*, thus denoting a person wearing a wool robe. Taking different regional and historical forms, sufism emphasizes an individual’s communion with the divine, the veneration of saints, and participation in religious brotherhoods. Each brotherhood has a teacher or master who initiates disciples into a particular set of rituals for reaching God.

Anthropology and Islam

In the 19th century, European expansion impacted the Muslim world, including forms of colonization and political domination. European historians and scholars of religion studied Arabic and other Semitic languages, primarily to understand the Bible’s ancient roots in the Middle East. Using a theoretical paradigm now called *evolutionism*, these scholars thought that societies such as the Bedouin, pastoral nomads in the Arabian Peninsula, represented a past way of life that was comparable to that of Abraham or Jesus. One such scholar, William Robertson Smith (1846–1894), may be considered a founder of the anthropology of religion as well as kinship studies. Though Smith’s evolutionist approach is no longer used in anthropology, he provided an early systematic description of the kinship and political organization of the Bedouin using ethnographic data. In writing about Islam, his main concern was in linking stages of religious development such as totemism,

animal sacrifice, and the development of monotheism. In his time, Robertson Smith’s ideas about religion were influential, and other scholars, such as Sigmund Freud in *Totem and Taboo*, borrowed much from him. Writing about Western scholarship on Islam, the late Columbia University Professor Edward Said and other critics of “orientalism” accuse 19th-century European scholars of overgeneralization, lack of historicity, and denigration of non-Europeans.

In the first half of the 20th century, forms of functionalism became dominant paradigms in British social anthropology and also were influential in the United States. Functionalism emphasizes the operation and interactions of social institutions as they maintain society. Anthropological studies during this period emphasized the study of small-scale societies and tended to ignore complex literate societies, where much historical work was necessary for cultural interpretation. In order to revive studies of complex societies in the 1940s, anthropologists labeled religious practices associated with standardized religious texts and authority “the Great Tradition,” while they labeled popular understanding and practice of religion “the Little Tradition.” Sufism, for example, was placed in the Little Tradition, ignoring the interpenetration of authoritative and popular understandings of Islam. E. E. Evans-Pritchard’s work on the Sanusi, a religious order among the Bedouin of Libya, is one of few monographs on the Islamic world written by an anthropologist during the functionalist period.

The situation changed dramatically in the second half of the 20th century, when significant theoretical and ethnographic works were written by anthropologists on Islamic subjects. Much of the work highlights the historically complex variability within different parts of the Islamic world through detailed case studies. Clifford Geertz, one of the most influential anthropologists of the period, has compared Moroccan and Indonesian variants of Islam. Michael M. J. Fischer focused on the Iranian revolution and role of Shiism in a major work that appeared soon after that event. Fischer conducted fieldwork in Qum, the center of Iranian Shiism’s religious establishment.

On May 14, 1948, the State of Israel declared its independence. Located in the Middle East, it is bordered by Lebanon, Syria, Jordan, Egypt, and the Mediterranean Sea. Although only about 290 miles long and 85 miles wide, Israel has a varied topography, including desert, fertile valleys, forests, and a coastal plain. It also contains the Dead Sea, the lowest point on Earth. Primarily a country of immigrants, Israel's population numbers approximately 6.5 million, about three quarters of which are Jews. Most Israelis live in urban centers, including the capital city of Jerusalem, Tel Aviv, Haifa, and Be'er Sheva, although 2% to 3% live in rural communities known as *kibbutzim*. The Israeli government is a parliamentary democracy comprising legislative (called the Knesset), executive, and judicial branches. Although Israel is most immediately understood as a geographically situated nation-state, it also refers to a concept of peoplehood shared by many Jews, for whom the notion of the "land of Israel" is indistinguishable from the "people of Israel." Both the geopolitical limits of the state of Israel and the cultural contents of the people of Israel are subject of much debate and contestation.

The political history of Israel can be understood as on ongoing engagement with the domestic and international challenges occasioned by war and peace. Some 24 hours after declaring independence, the armed forces of several neighboring countries, including Syria, Jordan, Egypt, and Lebanon, invaded Israel. This conflict, known in Israel as the War of Independence, lasted approximately 15 months and concluded with

armistice agreements negotiated under United Nations auspices. Under these agreements, Jordan took control of the West Bank, and the Gaza Strip came under the administration of the Egyptian government. Jerusalem was divided, with the eastern portion, including the Old City, going to Jordan and the western portion to Israel. However, Israel regained control of these territories after the Six-Day War of 1967, which also resulted in the Golan Heights moving from Syrian to Israeli control. In October 1973, the nations that had lost land in 1967 regained significant portions of what they had lost as a result of the Yom Kippur War (so-named in Israel because it coincided with the Jewish High Holy Day of Yom Kippur). While Israel and its neighbors have continued to do battle in the ensuing years (e.g., Lebanon in the early 1980s and Iraq in the 1990s), the greatest challenge to peace in Israel at the turn of the 21st century is that of Palestinian self-determination. In 1993, following several years of Palestinian insurrection known as the *Intifada*, Israel granted limited autonomy to the Palestine National Authority, led by former leader of the Palestinian Liberation Organization. On September 28, 2000, tensions between Israelis and Palestinians once again reached a flashpoint when Israeli leader Ariel Sharon visited the Temple Mount, Judaism's holiest place. Muslims refer to this site as *Haram al-Sharif* and regard it as one of Islam's holiest places. Since that time, Palestinians have continued to challenge Israeli authority, using both political channels and violence in an effort to obtain sovereignty.

In many ways, the ongoing disputes about the geographical borders of Israel the nation-state are directly tied to the notion of Israel as a people. While the term *Zionism* is usually construed to refer to the movement to establish a Jewish state, it has multiple connotations. Formally organized by Theodore Herzl in 1897, Zionism arose in the late 19th century in response to growing anti-Semitism in Europe and sought to reestablish a Jewish homeland in Palestine. Today, Zionism focuses on supporting and developing the state of Israel. However, the goal of establishing and maintaining a Jewish sovereign state necessitates a view of Jews as a people. In this view, Zionism positions Jewish history as central to the notion of Israel. Since so much of Jewish history has been characterized by persecution based on religious "otherness," there are also Zionists who emphasize the centrality of shared religious experience to the notion of Israel. However, traditional/Orthodox Jews view the geography of the

Source: FreeStockPhotos.com.

state of Israel as immutable. In the Torah, Judaism's holiest text, *Eretz Israel* ("the geography") is the Promised Land, given to Israel (the people) by God. The belief in Israel as a people undergirds the state of Israel's "Law of Return," under which Jews from any nation can claim and qualify for Israeli citizenship. Under the Law of Return, large numbers of Soviet Jews immigrated to Israel in the 1970s and 1980s, as did many Ethiopian Jews in the late 1980s and early 1990s. The latter of these, in particular, have had difficulty assimilating into Israeli culture, provoking many questions domestically about the limits of Israel as a people.

The limits and challenges to defining Israel as a people are also reflected in the conflicts between religious and secular Jews in Israel. In the eyes of some scholars, the divide between religious and secular Jews in Israel is even deeper than the divide between Israeli Jews and Arabs. According to Sandler, the divide can be defined in "the postmodern language of the politics of identity," with each side looking at the other side and defining itself as the other's opposite. The challenge presented by the secular-religious divide is not merely symbolic, however. This conflict in the definition of Israel as a people also has implications for Israel as a nation-state. The question of Palestinian sovereignty, for example, is inextricably

connected, since the notion of *Eretz Israel* is biblically revealed, and therefore not negotiable, to those on the religious side of the divide. There is a reciprocal relationship between Israel as a geopolitical phenomenon and Israel as a group identity, and the challenges faced in one sphere also inform the course taken in the other.

JARMO

Jarmo (Qal'at Jarmo), located in modern northern Iraq, is one of the oldest Neolithic agricultural settlements in the Middle East. Excavations here yielded much information on human society's transition to sedentary agricultural practices. University of Chicago archaeologist Robert Braidwood spent several seasons between 1948 and 1955 excavating the village that dated between 9,250 and 7,750 years ago (7250 and 5750 BCE). The introduction of ceramic vessel technology in Jarmo's later levels suggests the site spanned two time periods that are known as the Pre-pottery and Pottery Neolithic.

The village of Jarmo consisted of mud brick, rectangular houses whose inhabitants subsisted on a diet of domesticated and wild plants, and animals. Domesticated plants included emmer and einkorn wheat, two-row barley, and lentils, while wild specimens included undomesticated wheat and barley, acorns and pistachio nuts. The villagers depended on domesticated sheep and goats for meat and dairy products as well as dogs to protect their herds. Villagers also hunted wild animals for resources and as protection; excavations revealed the remains of cattle, fox, lions, and leopards. Villagers depended primarily on flint, obsidian, bone, and eventually ceramic to make the everyday tools for food preparation, house construction, and hunting.

At the time of its discovery, Jarmo greatly expanded anthropology's limited understanding of early food-producing villages. In periods prior to the founding of agricultural villages, human societies practiced hunter-gathering subsistence in relatively small nomadic bands. As they became increasingly sedentary, human societies developed strategies to manage the wild crops and animals more efficiently. With increased investment in sedentary agriculture, settlement became permanent and villages saw an increase in population, disease, and

political complexity. Braidwood's careful excavations at Jarmo revealed that this Neolithic "Agricultural Revolution," as it has been popularly coined, took several thousand years to complete, a fact made obvious by the presence of both domestic and wild plant and animal species in the village. Agricultural villages like Jarmo were the economic and political predecessors of the first Mesopotamian cities that would arise in the region beginning in the fourth millennium BCE.

Braidwood's excavations at Jarmo represented a watershed event in archaeological research as it was the first time an archaeologist had employed an interdisciplinary research project designed to understand the origins of food production. In addition to archaeologists, the Jarmo team consisted of specialists who studied the region's geology, the ancient climate, and plant and faunal remains. The innovative Jarmo project served as an example to both Old and New World archaeologists who were only beginning to pursue more sophisticated research on such important revolutions in human society as the origins of agriculture, urbanism, and craft production.

 JAVA MAN

In 1887 a Dutch anatomist, Eugene Dubois, joined the Dutch army as a means to bring him to south Asia to hunt for the “missing link.” His major interest was the theory of evolution proposed by Charles Darwin in 1854. Dubois received an assignment in the Dutch East Indies (now Indonesia) where he assumed humans had evolved. He arrived first in Sumatra where he was able to obtain financial support from the army and began excavating in a number of caves. Initial results, however, proved disappointing, since the soil deposits were too young to yield evidence of the earliest humans.

Dubois heard news of some exciting new finds of extinct mammals in eastern Java and moved his research to the Solo river valley in East Java. The Dutch army supported his excavations by providing him with two engineers and fifty indigenous forced laborers. In 1891 Dubois’s workers found a skull cap (the majority of both parietals and the upper portion of the occipital bone) along the Solo River near the village of Trinil. A year later and approximately 50 feet from the skull cap, a femur (upper leg bone) was found. The find of the femur was proof to Dubois that what he had found was an “upright walking ape-man” which he named *Pithecanthropus erectus*, today known as *Homo erectus*. In 1894 Dubois published an article stating that *Pithecanthropus erectus* was a distant ancestor of modern man and had lived almost a million years ago. At the time authorities were of divided opinions; they regarded the find as either from a man, an ape, or an ape-man. The criticism from the scientific and religious communities caused Dubois to hide his discoveries under his house for 30 years.

In 1888 and 1890 two human skulls were recovered at Wadjak, about 65 miles from Trinil. Wadjak I was found by a Dutch mining engineer while prospecting for marble. Wadjak II was found by Dubois at the same site. The Wadjak skulls are modern *Homo sapiens* and less than 20,000 years old. These finds were reported only in the quarterly and annual reports to the Dutch East Indies government but not to the scientific community. Dubois withheld these specimens for fear that they would be associated with the Trinil finds. In 1920 Dubois publicly announced the skulls when another researcher claimed to have discovered the first *proto-Australian*.

In 1907–08 an expedition conducted by Selenka, another Dutch scientist, excavated 10,000 cubic

meters down to 40 feet below the surface at the same location as the original Trinil site without finding any more remains of *Homo erectus*. The skeletal remains of hundreds of species of extinct animals were found and returned to the Netherlands.

In 1991, exactly one hundred years after Eugene Dubois’s workers discovered *Homo erectus* (*Pithecanthropus erectus*), a museum opened at the site of Trinil. The museum displays the bones of mammals found at Trinil, such as mammoth and an extinct form of bison. It also displays some of Dubois’s original documents and photographs, as well as replicas of the original skull, molar, and femur of *Homo erectus*.

The original fossil specimens of Dubois’s excavations can be found in the natural history museum at Leiden University in the Netherlands. One of Dubois’s most important contributions to understanding the natural history of *Homo erectus* is overlooked by most researchers: Dubois’s Indonesian workers collected and preserved hundreds of species of extinct animals and plants that can be studied at Leiden University.

 JEWELRY

Jewelry consists of any ornament that is placed on the body for any symbolic reason. Ornaments can be made of metals, shells, beads, textiles, clay, gems, stone, glass, or any components extracted from animals or plants.

Sometimes worn as talismans, jewelry is found among every culture and society in forms ranging from rings, armlets, bracelets, necklaces, and ornamental piercing to broaches, headdresses, and hair clips.

Jewelry plays many roles within cultures. It may be used to adorn the body, to express wealth, as a method of payment or trade, to convey social or spiritual messages or as a tool of creativity. It is possibly one of the earliest forms of art.

Early Evidence of the Presence of Jewelry Among Cultures

The first indication that jewelry was an important element in human society is traced back 100,000 years ago during the Ice Age, when human bodies were buried with funeral gifts including jewelry. Archaeologists have found the remains of inorganic materials such as stones, fossils, and clay that were used in the making of jewelry during the Paleolithic Age dating between 50,000 and 10,000 BC. Other materials suspected to be used during this time to make jewelry include bones, horns, shells, and amber. The jewelry created was in the forms of necklaces, amulets, bracelets, earrings, and headdresses made from carved ivory, seashells, and antlers, as well as animal and fish teeth and bones. Linear and stipple designs and carvings replicating animals forms suggest special attention to the detailing of jewelry. In Europe, rock paintings left by hunters and gatherers during the Ice Age consist of drawings and images of human forms decorated with numerous colorful and creative ornaments on the heads, necks, arms, and legs. Facial ornaments such as earrings, lip, and nose ornaments were also depicted on these individuals. These findings suggest that jewelry creation and application were quite significant during this time.

The Neolithic Age was an evolutionary period in the production of jewelry. Materials used in making ornaments became increasingly available with the rise of horticulture, and improvements in living conditions led to population growth. Advancement in toolmaking enabled artisans to create more complex pieces of jewelry as well as increase production. Materials such as spondylus (mollusk) shells, amber, marble, copper, and gold were used in the exchange of goods. With these changes in effect, other materials and procedures were used to create jewelry. Pearls, precious metals, and stones were carefully cut, shaped and polished into works of art and forms of wealth.

In comparison to earlier periods, more time was spent creating pieces of jewelry which reflected craftsmanship and artistic ability. The advancement of jewelry making also introduced the use of chains and the heating, hammering, and molding of metals into specific forms and designs. Widespread trade played a significant role in the development of jewelry making. The style and materials used in construction were representations and indicators of regions and areas in which jewelry originated. During this period, jewelry specific to particular regions is found over extensive distances. An example of this distribution involves the discovery of spondylus shells, copper and gold jewelry originally from the Mediterranean, but found in Central and northern Europe.

The Bronze Age generated specialized fields such as metal work and other technical processes including heating and lighting. Knowledge and experience were key elements in the growing social divisions of labor. It is suggested that this is the period in which primitive societies began to dissipate. Two Bronze Age cultures stood out in comparison to others in association with jewelry production. The first, the Aunjetitj Culture, created simple forms of jewelry comparable to jewelry made in the Neolithic Age. In the earlier stage of the Bronze Age, popular forms of gold rings were produced by the twining or twisting of wire. Some archaeologists suggest that some form of social stratification existed as evidenced by discoveries of “princess graves” in which individuals were buried with numerous pieces of jewelry made of gold. The second, the Tumulus Culture, formed at the peak of the Bronze Age, left evidence of similar burial customs as well as other material items. The techniques and artistic quality, in contrast to the Aunjetitj Culture, employed bronze casting and the work of the bronze smith. These techniques were improved and the processes advanced with the manipulation of the metals.

Jewelry in Contemporary Times

During the 18th century, jewelry was produced mainly by craftsmen and small manufacturers. England advanced economically compared to other countries, producing jewelry of better quality in the early 19th century. Machines and factories began to replace hand craftsmanship and small manufacturing, a trend that spread to other parts of Europe, Japan, and North America. Advances in stonecutting techniques began in the 18th century and continued

to the mid-19th century. The Bourgeois Revolution brought with it the evolution of peasant jewelry. Imitation jewelry and cost-effective jewelry began being produced and worn by lower social classes, thus overcoming the obstacles that allowed only high-class individuals to wear jewelry. Jewelry began to take on additional purposes and representations, becoming viewed as a statement of personality and independence. The use of silver was a common feature among peasant jewelry. Gold was used sparingly. Gold-plated silver, silver-plated copper, and brass alloys were used among the poorer peasants. Colored gems, stones, and glass were used to brighten up ornaments.

The evolution of jewelry-making continued, from mass production and replication processes to the colors and designs used to create pieces of jewelry. Today jewelry is affordable to most economic classes through mass production of imitation jewelry. Although association of jewelry with the higher classes has decreased, it is still present. Only a small amount of the world's population can afford to adorn itself with various precious gems and stones. The difference between past and present persists by virtue of the significance attributed to names of designers, companies, and quality of materials. Public attitude and the significance of jewelry still varies from culture to culture depending on social, economic, and cultural situations.

The Role of Jewelry in Society

Within a social context, jewelry plays numerous roles. It has been used as a teaching tool to communicate knowledge, to explain and recall histories and events; for example, in hunting tribes amulets were given to poets or singers to wear during a performance in order to transfer knowledge. Jewelry is also commonly used in identifying individuals. Soldiers often wore bracelets and necklaces as identification which was sent back to home to family or next of kin upon the soldier's death. In Africa, jewelry expresses information about an individual. For example, Tuareg women wear bracelets, rings, and silver beaded necklaces given by the husband at marriage. Jewelry is used to signify whether a woman is married, divorced, or widowed.

Jewelry signifies traditional and religious beliefs. For example, the Tuareg people of Africa regard the use of a triangle as a symbol of protection; thus, the triangle is a popular jewelry form and is worn frequently in order to protect against evil forces.

Other benefits are associated with the wearing of particular materials. Silver is believed to bring happiness, agates are believed to be healing stones, and specific shells are used as fertility charms. Gold was once believed to attract misfortune, but is now frequently worn, denoting cultural adaptation. Silver is still considered to be a classic form of jewelry but gold has become more accessible and affordable than in the past, which has resulted in its increased use.

South American jade in the form of a frog or a bird was thought to bring the wearer the gift of life. Ancient Greeks and Romans wore images of Medusa to destroy evil forces, and dog's teeth to ward off illness. Members of many religious groups wear pendants, medallions, amulets and mandalas to identify themselves with a particular religion or sect, as a means of protection, or to show loyalty.

Jewelry has been used frequently in trade and as a sign of wealth. In Egypt, artifacts suggest that the role of jewelry played an important role for both the living and non-living. Pharaohs and the upper class accumulated large amounts of jewelry; however, not all jewelry was worn. It seems that jewelry played an even more important role in the burial rites of an individual. High-status individuals such as pharaohs and kings were often buried with an enormous amount of jewelry consisting of colorful objects, lapis lazuli, or glass with gold, mostly in the form of a scarab. The scarab was the classic universal charm or amulet and a principal theme in Egyptian ornamentation. The scarab was associated with the sun god Ra and therefore acquired magical significance. In Egyptian society, most artisans were exiled from the Valley of the Living, forced to live and work in the Valley of the Dead, creating masterpieces for the afterlife.

Unlike the Egyptians who strongly associated jewelry with the divinity, the Ptolemaic Romans strongly associated jewelry with the living. Jewelry was used as a tool by which to express or signify the owner's wealth. To make no mistake of ownership, the names of the owners were engraved into the pieces of jewelry.

It has been suggested that Roman women were the first women to wear jewelry freely, due to their social and economic status. Jewelry worn during this time consisted of necklaces, bracelets, rings, earrings, broaches, crowns, and anklets. Romans took comfort in their status and expressed their economic wealth by wearing jewelry to communicate their socioeconomic status. Gold was a predominant material used in Rome. Roman jewelry patterns and

forms were straightforward and bold in design. Greater emphasis was placed upon size and weight than on intricate design.

Beads are the materials most commonly found in the Indus Valley, but cave paintings dating back to the 8th century AD depict Buddhist women wearing gold crowns and numerous necklaces. Other sculptures from the 12th century include ornaments such as dangling pearl earrings and gems deeply cut in black stone. In India, jewelry symbolized the ruling class's power; an immense amount of power was expressed through a large quantity of jewelry. Materials associated with the history of Indian jewelry include pearls, diamonds, rubies, emeralds, lignum, aloes, and coral. Indian princesses were believed to have worn lengthy necklaces made of a variety of jewels such as pearls and gold, gem-set ornaments. An abundance of rings, bracelets, armlets, earrings, and waistbands were covered with magnificent jewels.

North American Indians originally used shell, turquoise, feathers, bearclaw, ivory, bone, and copper as the essential materials in creating jewelry. Exotic materials used were jade, freshwater pearls, particles of mica, and pieces of meteorite. Today, contemporary Native American jewelers use gold, platinum, diamonds, emeralds, opals, rubies, natural turquoise, coral, sugilite, chrysocolla, lapis lazuli, spiny oyster, and hardwoods. Much of the jewelry worn by Native Americans was, and still is, associated with the spiritual world and relationship of humans to Mother Earth in a celebration of all living things.

Although most jewelry produced today is mass-produced, there remains an art to jewelry making. Craftsmen, artisans, and artists continue to be inspired by old styles and designs. Individuals and families have maintained traditional procedures, techniques, and knowledge to be passed on to future generations. Jewelry is a key to cultural continuity and to rediscovering and reinterpreting culture over the generations.

The title *Jews* has multiple variations in meaning. Jew is a term that can refer both to adherents of the religion Judaism and to members of an ethnicity (those who are Jewish). In the religious sense, Jews are followers of Judaism, whether or not they are ethnically Jewish. In the ethnic sense, Jews are those whose familial identification links them to the “peoplehood” of Jews. Ethnic Jews include both religiously observant Jews and those who, while not practicing Judaism as a religion, identify themselves as Jews culturally or through their ancestry. In Jewish law, or halakhah, there are two criteria for defining someone as a Jew, either one of which is sufficient. If one is the child of a Jewish mother, or if one converts to Judaism in accordance with Jewish law, then one is halakhically recognized as a Jew. This standard is mandated by the Talmud, the record of Oral Law that elaborates the Torah (also known as the Hebrew Bible, the Five Books of Moses, the Pentateuch, or, in Christian texts, the first five books of the Old Testament). However, in the second half of the 20th century, two theologically liberal branches of Judaism, Reform and Reconstructionist, have shifted position on the matter of Jewish identity. They now recognize as Jews those who call themselves Jews, although they meet neither halakhic criterion. Based largely in the United States, these two denominations no longer require one to have a Jewish mother if one's father is a Jew, nor do they require converts to follow traditional/Orthodox conversion procedures. This shift has produced a significant rift among various groups of Jews debating the question, “Who is a Jew?” Such Reform and Reconstructionist Jews, as well as secular/ethnic Jews, consider themselves Jews, but are not necessarily viewed as such by Orthodox and Conservative Jews. In addition, many Reform Jews outside the United States maintain traditional definitions of Jewish identity, rejecting American Reform Judaism's adaptations.

Given these complexities of identity, one must think broadly when defining “the Jews.”

Despite these divisions, there are four generally recognized denominations (also called movements) within religious Judaism: Orthodox, Conservative, Reform, and Reconstructionist. Orthodox Jewish movements are those that emerged as a response to the cultural and religious changes prompted by the European Enlightenment, which included the political and social emancipation of Jews. The term encompasses traditionalist movements that sought to resist the influences of modernity and religious reform that characterized this era. The term is not typically used to denote Jewish traditionalism prior to the modern era, nor is it used in the context of Jewish communities unaffected by the emergence of Reform Judaism (for example, Jewish communities in North Africa). Orthodox Judaism is viewed by its adherents as the “true” or “authentic” Judaism since it follows the provisions of halakhah codified in the Torah and Talmud. While maintaining broad similarities in ritual and theology, Orthodox Judaism is comprised of many groups with both intersecting and diverging beliefs and practices. For example, ultra-Orthodox Jewish movements such as Haredim and Chasidim differ from Modern Orthodox movements in the extent to which they make allowances for living in the modern world. In addition, there are differences in beliefs in many areas, including the role of women in Judaism, the significance of the State of Israel, and relations with non-Orthodox Jews.

In contrast to Orthodoxy, Reform Judaism embraced the changes brought about by the European Enlightenment and Jewish emancipation. There are many varieties of Reform Judaism, but all assert the legitimacy of change in Judaism. As such, Reform Judaism has continually undergone revisions in practice and theology, since there is no irrefutable and absolute codification of Jewish law in Reform doctrine. The American Reform acceptance of patrilineal descent, which rejects the halakhic criterion of matrilineal descent in determining Jewish identity, illustrates the sharply contrasting positions held by Reform and Orthodox Judaism regarding strict interpretation of traditional Jewish sources of authority. While some Reform religious leaders promote adherence to select components of halakhah and traditional Jewish theology, others consider such practices to be inconsistent with Reform principles. Given Reform Judaism’s emphasis on personal autonomy in matters of faith, both of these positions are considered acceptable.

Conservative Judaism occupies some of the vast middle ground between Orthodox and Reform Judaism. It, too, emerged as a reaction to the changes precipitated by the European Enlightenment and Jewish emancipation. In Europe, this movement was originally called Positive-Historical Judaism, and is still known as the Historical movement. In the United States it became known as Conservative Judaism. In Israel and England, it is referred to as Masorti Judaism. Conservative Judaism embraces a strong commitment to traditional elements of Jewish observance, while simultaneously accepting the potential usefulness of contemporary critical (i.e., secular) scholarship on Judaism’s sacred texts. As such, Conservative Judaism maintains a commitment to halakhah, but sees halakhic authority as continuing to evolve in the modern era.

Reconstructionist Judaism, which emphasizes Judaism as a religious civilization, was developed by Mordecai Kaplan, an American rabbi trained in the Conservative tradition, during the 1930s. It formally assumed the status of separate denomination when the first Reconstructionist Seminary was founded in 1968. Like Reform Judaism, Reconstructionism privileges personal autonomy in matters of faith over traditional understandings of Jewish law and theology. However, this movement also promotes a number of traditional practices, including the observance of holidays, the use of Hebrew prayer services, and the wearing of yarmulkes (i.e., skullcaps). In Reconstructionism, individual congregations are free to accept or reject these practices, based on the wishes of their congregants. There are some significant theological differences between Reconstructionist Judaism and the other three major movements. For example, Reconstructionism rejects the idea that the Torah was delivered by God; rather, the Torah is considered a product of the social and historical development of the Jewish civilization.

Although there are religious Jews of many ethnicities and nationalities, there are two generally recognized ethnicities that are distinctly Jewish: Ashkenazim and Sephardim. Ashkenazim are descended from Jews in Eastern Europe, as well as Germany and Austria, while Sephardim trace their ancestry to the Mediterranean region, including Spain, Portugal, and North Africa. The traditional language of Ashkenazic Jews is Yiddish, while Ladino is that of Sephardic Jews. Neither of these languages is spoken widely today, and Ladino has all but disappeared from use. While

there are many points of overlap in customs between the two groups, there are also many points of divergence. For example, it is customary among both groups to eat foods fried in oil during the festival of Chanukah, but the holiday's signature food differs: for Ashkenazim, it is the potato pancake (called a *latke*), while Sephardim indulge in fried donuts known as *sufganyot*.

In the west, many secular Jews base their Jewish identities on shared history, a sense of peoplehood, and an investment in cultural

Judaism. Some elements of cultural Judaism include specific foods (many of which have been incorporated into the non-Jewish mainstream, such as bagels), distinctive folk music called *klezmer*, and a particular style of Jewish humor (for example, Woody Allen). For many secular Jews, pride in the survival of the Jews as a people, through many historical episodes of persecution, expulsion, and attempts at annihilation, serves as the foundation of their sense of Jewishness. Some of the most notorious examples of such threats to Jewish survival include the Spanish Inquisition, Russian pogroms, and the Nazi Holocaust. In general, ethnic Jews reject the notion of "racial" Judaism, given the history of this concept's relationship to anti-Semitism.

Among the consequences of the resolution of the Second World War was the establishment of the State of Israel as a Jewish homeland. After over two thousand years spent largely in Diaspora, Jews established their own nation, one in which all Jews are guaranteed citizenship irrespective of their nation of birth. However, Israel's Law of Return (the statute granting citizenship to all Jews) requires some level of agreement about the answer to the question, "Who is a Jew?" Given the significant rifts that exist between religious Jews and ethnic Jews (as well as those among the various denominations of religious Judaism), the answer to this contentious question has taken on political as well as cultural dimensions. In Israel, where most Jews are either

Reform or secular/ethnic, the halakhic criteria for determining Jewish identity (supported by the Orthodox movement) serve also as the political criteria for determining immigration eligibility under the Law of Return.

Some observers worry about the long-term impact of the rifts among Jews on Jewish unity and the survival of Jewish "peoplehood." Is there still a central link connecting all who claim to be part of "the Jews"? If so, can the center hold, given the varying definitions pulling from the periphery? Since the establishment of the State of Israel, some view Judaism as a matter of nationality. However, Jews can be (and are) citizens of many nations, and non-Jews can be (and are) citizens of Israel. Others view Judaism as a matter of culture, since many consider themselves Jewish without being religious. For those religious Jews who are faithful to halakhic law and traditional Jewish theology, even those raised in a culturally Jewish environment, they are Jewish only if born to Jewish mothers or converted through an halakhically approved process. The contemporary situation of the Jews is best defined as one in flux, with the outcome of the identity challenges still to be determined.

JEWS AND PSEUDO-ANTHROPOLOGY

When anthropology emerged as a science in the mid-to late 1800s, it was almost immediately corrupted by the biases of some of the individuals who pioneered it. The politics in Europe at the time had shifted heavily toward anti-Semitism. Because anthropology was a fledgling science, it was easy for these prejudices to infiltrate because there were no scientific precedents to refute them. Initial scientific classifications of the human species were ridden with racism as well as social and religious biases. Presented as scientific fact, these prejudices became established in the ideology of European society.

While there were anthropologists trying desperately to refute these racist notions, they found themselves deprived of support and funding because they did not share the views of those in power. Although many scientists in the field of anthropology were of Jewish descent, few of them spoke out for fear of being further repressed. Many of the dissenters were innovators in anthropology who emphasized the role of cultural and social environments over biology and

inheritance. Scientists such as Franz Boas, Melville Herskovits, and Margaret Mead realized that racism was used as a political tool, distorting the scientific facts regarding the physical variations within our human species.

The new science of anthropology was used by some to justify already established prejudices against certain ethnic groups, in particular the Jews. Some claimed that the Jews were not only inferior but also not even a part of the species. These radical racial classifications made it easier to look at those that are physically different as being genuinely subhuman. Even Darwin's theory of evolution, with its explanatory phrase "survival of the fittest," was seen as a reason for the Jews to be eliminated in order for European culture and society to prosper. This context can in some way help to explain how so many sat by as an entire group of people were being systematically killed off.

At the beginning of the 20th century, it was argued that there were between three and five (or more) distinct races within Europe; this discrepancy in number indicates that the facts behind these claims were less than reliable. Textbooks published in the 1920s varied greatly, but contained similarities in the ways in which they presented characteristics of each race. Surprisingly, very specific details were often provided as to the physicality of a person in each of these classifications. These texts provided average heights, weights, and even cranial circumferences for entire groups of people. Such measurements could never have been taken using the appropriate scientific method to make such generalities, particularly within an evolutionary framework.

Five of the most common groups described were the Nordic, Mediterranean, Alpine, Dinaric, and East Baltic races. It is evident from reading such descriptions in early 20th-century literature that there were obvious biases. The Alpines and Baltics were often described as dull in appearance, the Dinaric race looked defiant, and the Nordics and Mediterraneans were characterized as sophisticated and elegant. Each description carries connotations that create a definite hierarchy with the Nordics and Mediterraneans on top and the Alpines and Baltics below.

This hierarchy was not restricted to the five European races. Jews were listed as a subdivision within each group. Jews were depicted as being shorter and narrow chested, with a diminished lung capacity. They were said to be brunettes with thick, hooked noses and bushy eyebrows. Their skin was often

described as swarthy and their chins were said to be pointy beneath a mouth filled with oddly shaped teeth. The general characteristics that describe those of Jewish decent were ridden with negative overtones that diminished the status of Jews within every society.

The intermixing between Jews and the rest of the European races is what angered some people the most; it is what the Nazi party used as propaganda in Germany to gain support for their anti-Semitic policies. Hitler himself stated that he felt Jews and humans shared a common evolutionary path. Yet, he believed that at some point that common path split, placing the humans and Jews on separate branches. By integrating scientific concepts, such radical statements can sound plausible to a naive society. Unfortunately, many physical anthropologists and biologists of this time period used their science to spread biases that were beneficial to the Nazi cause.

Other new fields of science, such as genetics, were emerging, and they would eventually provide information that would be used to dispute these racial classifications. The genetics revolution in racial theory shifted the focus from physical characteristics (phenotype) to the DNA molecule (genotype); however, with the onset of World War II, some people that were able to experiment in these fields were the Nazis themselves. It has been discovered since that their methods of experimentation were even more atrocious than the theories that fueled them. The horrors of the Holocaust motivated some in the scientific community who had previously refrained from voicing opposition to take serious action. Fortunately, the field of genetics continued to advance and began to amend the public's perception regarding race and racism.

Today, anthropology has a more comprehensive view of our human species. By incorporating the studies of the physical and cultural aspects of humanity, one is able to see that humankind as *Homo sapiens sapiens* is a unified species sharing the same genetic foundation, but manifesting major sociocultural differences. No longer can groups of people be placed into a hierarchy based on physicality. As anthropologist and philosopher H. James Birx states: "There is only one human race, or there are over 6.5 billion human races on earth."

JOHANSON, DONALD C. (1943–)

American paleoanthropologist Donald Johanson is most notable for his discovery and interpretation of the fossil hominid *Australopithecus afarensis*.

Originally born in Chicago, Illinois, of Swedish immigrants, Johnson faced adversity early in life. After the death of his father when Johanson was 2, his mother moved him to Hartford, Connecticut. Johanson's interest in anthropology was stimulated early in life by Paul Leser, a neighbor who taught anthropology at the Hartford Seminary Foundation. Through exposure to various cultures, Johanson's interest in our species' past developed quickly. Although Johanson decided to become an anthropologist in high school, Leser discouraged his anthropological interest in favor of his aptitude in chemistry. Encouraged to pursue science, Johanson attended Illinois State University for chemistry; however, his interest in anthropology grew stronger, eventually leading him to switch majors from chemistry to anthropology, whereby he participated as an archaeologist in the Midwest. Not completely satisfied with the coursework at Illinois, Johanson eventually transferred to the University of Chicago, where he received all of his degrees (BA, MA, and PhD).

In addition to his scholastic endeavors, Johanson was named curator at the Cleveland Museum of Natural History in 1974 and subsequently developed its affiliated Laboratory of Physical Anthropology. Johanson later relocated to Berkeley, California where he founded the Institute of Human Origins. At this publication date, both Johanson and the Institute of Human Origin are at Arizona State University, Tempe, Arizona.

Contributions and Perspectives

Johanson's most significant contribution was the discovery and interpretation of the fossil hominid, which he named *Australopithecus afarensis*. Although his first discovery was dubbed "Lucy" during the excavation, the Hadar collection AL 288–1 would prove to be a single specimen that challenges the traditional taxonomical sequence of the human evolutionary line.

Discovered during what could be considered the latter half of the great hominid discoveries, in the early 1970s, Johanson set out to search for fossil hominids in Hadar, Africa. The area of Hadar was perfect for recovering fossils. Hadar was once an ancient lake bed that is now rock, sand, and gravel. Due to the soil's inability to absorb rainfall, runoff tends to erode the soil, uncovering fossils that lie underneath. Johanson's first field season at Hadar yielded a proximal tibia, a condyle, and a distal femur. Johanson quickly realized the relationship among the three specimens; discounting human or monkey remains, the knee joint specimen had to be a fossil hominid. Confirmed by Mary and Richard Leakey, this knee joint was the first to be analyzed by anthropologists. An early estimated age of 3 to 4 million years gave Johanson proof of the oldest bipedal specimen to date, causing debates and a reanalysis of hominid phylogeny.

Although the initial description of this small bipedal creature (for the analysis was far from complete) had yet to gain acceptance by the scientific community
